The symptoms of a floating liver are a distress and feeling of weight in the region of the liver. Often a good deal of tympanites and symptoms of intestinal indigestion. The action of the bowels seems to vary, even in the same individual; sometimes diarrhea and sometimes constipation is present. The nervous symptoms can not be all enumerated; they are as numerous as we get in hysteria. They are (as we find in all reflex nervous condition of other organs), headaches, restlessness, hypochondriasis, gastric disturbances, etc. Quite a few of these cases cause no symptoms except the sensation of weight, and patients were quite comfortable when wearing a bandage.

Few attempts have been made so far to relieve this condition by operative interference. In the case of Dr. Binnie, a simple exploratory operation was made and the diagnosis cleared up. Others made exploratory operations, but few attempts at a radical cure. Richelot was the first, I think, who deliberately operated to cure.

In cases of general enteroptosis the abdominal bandage will be valuable, as recommended by Einhorn. In such cases operation will be of no benefit, as we have to deal with a general condition of the system. My case is as follows:

Mrs. R. Elkhart, Ind., a patient of Dr. Mast, aged 48, passed the menopause; married a second time, but never had children. She is a hard-working woman, weighs about 220 lbs., never has been seriously ill, but has had the usual symptoms of the menopause well marked. During the last year she has been troubled with pain in region of the liver extending down to the pelvis, a sensation of fulness and distress; sometimes she was obliged to keep in bed for a half day to two days; occasionally she was jaundiced for a few days. All symptoms indicated some diseased condition of the liver, but no symptoms of gallstones, no severe colic; simply a feeling of fulness and distress. She was inclined to be constipated; her digestion was good, although she complained a good deal of gas. The nervous symptoms were also well marked, especially hypochondriasis and despondency, as is often found in disturbances of the digestive system.

**EXAMINATION:** The woman being heavy and stout, it was difficult to make a positive diagnosis of abdominal trouble. Percussion on the right side down to the pelvis indicated a tumor, or solid mass, the character of which could not be made out; it might be an enlarged liver, tumor of the kidney, an ovarian tumor developed in that direction, or possibly a long pedicled fibroid. It might also be a malignant growth, although the general appearance of the patient would discredit such condition, or one of those very rare tumors, such as a hydatid or a cyst of some other organ attached to the right side. The growth did not seem movable. I did not express an opinion of its character, but suggested an exploratory operation.

**OPERATION:** She was operated on April 24, 1900. An incision made at the outer edge of the rectus two inches below the ribs and downwards for two and a half inches. After cutting through a thick layer of fat and opening the peritoneum, the enlargement proved to be the liver. The right lobe was much enlarged and hanging down to the brim of the pelvis. It could be easily replaced in its normal position and then projected about two inches below the ribs. There were no gallstones. All other abdominal organs seemed normal.

It seemed to me that the only thing to do was to fix the liver as near as possible in its normal place. I therefore scraped as thoroughly as I could the anterior side of the liver and the anterior wall of the peritoneum, so as to get it thoroughly denuded of epithelium and to allow adhesions to take place. I then brought the raw surfaces together, grasped the coronary ligament and brought it forward and stitched it to the upper angle of the wound. I then closed the abdomen with dry sterilized catgut in layers and dressed the wound as usual. The patient made an uninterrupted recovery. Nearly all her symptoms had disappeared when she left the hospital on the 20th day. I heard of her three months later, still much improved, but occasionally troubled with gas.

I report my case for the purpose of calling attention to the condition, which is certainly rare, and still, by being on the lookout for it, perhaps, a good many more cases would be found than we suspect, especially in these chronic abdominal troubles with no marked symptoms.

I also report it for the purpose of calling attention to the fact that operative procedure will offer a radical method of cure.

## SOME ACUTE DISEASES OF THE EAR; THEIR DIAGNOSIS AND TREATMENT.\*

PHILIP HAMMOND, M.D.

Assistant in Otolaryngology, Harvard University; Assistant Aural Surgeon,  
Massachusetts Charitable Eye and Ear Infirmary, etc.

BOSTON, MASS.

It is my purpose in presenting this paper to call to your attention some of the more common conditions which confront us when we have occasion to examine the ear. The two most frequent symptoms which drive the ordinary person to seek medical attention for this organ are pain and deafness, and to treat either successfully we must remember that we have to deal with symptoms and not diseases. Take the pain, for instance, and we find that it may come from an abscess of the middle ear, from an ulcerated tooth, from a furuncle in the canal, or perhaps tonsillitis or rheumatism, or some other general disturbance is at the bottom of it. We learn to recognize that deafness, too, is but a symptom, and that it may come from one of many causes.

In examining a case of earache, we thoroughly inspect the drum, noting in the first place the presence or absence of normal appearances. If we detect any congestion we at once conclude that here is sufficient cause for pain and proceed to treat it. In the absence of any inflammation, we know that it is not possible for such an ear to give rise to pain, and we must look elsewhere for the cause. The most common cause of earache, aside from actual inflammation of the ear itself, is due to the presence of a carious tooth, and this is usually found to be a lower molar on the affected side.

The presence of a furuncle is usually easily demonstrated, as we have a sharply localized swelling in the canal which is extremely sensitive to the touch, and which renders examination rather difficult. In the early stages the drum can be seen, and the fact that it is not inflamed aids us in the diagnosis. Very rarely the furuncle will assume such proportions as to simulate a mastoid swelling, the ear standing out from the side of the head, and there may even be fluctuation behind the ear. Diagnosis in these cases is often difficult and it may take a day or two to clear up the question.

Treatment should be directed toward giving the patient comfort. Repeated hot applications, the use of a tight tampon of cotton, dipped in a 4 per cent. solution of carbolic acid in glycerin, placed in the canal, and

in extreme cases of a long, slim flaxseed poultice, curved about the ear in the shape of a horseshoe, have given the best results in the writer's practice. Incision should be resorted to only when the furuncle is pointing. Premature opening apparently does no good, and many think that it favors the formation of more infected areas. The patient's general health should be attended to, and tonics given. Above all, any scratching or fingering of the ear should be prohibited.

Children are the most frequent sufferers from earache, and perhaps the majority are subjected to all kinds of home treatment before the physician is called. Their unusual susceptibility is due to the fact that there is a certain amount of adenoid tissue in the naso-pharynx of almost every child, and in some this is abnormally developed, with the result that the child is continually getting head colds. With each cold nasal respiration is more or less blocked, the growth swelling so as to obstruct the naso-pharynx, and in this way the Eustachian tube becomes involved. As a direct result we have one of two things. The child may have severe pain with development of an abscess, or it may become deaf from closure of the Eustachian tube and subsequent exudation of serum into the ear cavity. The first is due to invasion of bacteria along the inflamed membrane, the second to the complete occlusion of the tube. We will take up the discussion of the latter condition first, leaving the suppurative inflammation of the middle ear for a few minutes.

Acute closure of the Eustachian tube is painless, and usually begins with a stuffy sensation in the head, followed by a more or less marked deafness. In the case of a child this may be attributed to stupidity. Sounds within the head appear to be very much louder than they really are, and to the patient his own voice sounds as if he were speaking with his head in a barrel. Inspection of the drum shows a darkened, retracted membrane, without any injection of the vessels. If the disease has progressed so far that there is already fluid within the ear, we may be able to make out its upper level through the drum.

In slight cases where there has been no exudation, the natural tendency is toward spontaneous recovery with the passing of the cold which caused the trouble. Repeated attacks, however, can not but result in organic changes in the ear, which later in life become apparent as the familiar dry catarrh of the middle ear, with very considerable deafness.

In the severer forms where an exudate has formed in the middle ear, treatment of the nasopharynx and inflation by means of Politzer's method will usually restore the hearing in a very short time. If the child is subject to these attacks, however, we must not look for a permanent cure until the adenoids, and particularly those around the Eustachian tubes, have been removed.

This collection of fluid in the middle ear is by no means confined to children, and sometimes we have very much greater difficulty in securing absorption in adults. If after about ten days of careful treatment of the nasopharynx, and inflations, the fluid has not disappeared, it may be advisable to perform paracentesis in the lower part of the drum, and then inflate, thus forcibly expelling the fluid. The hearing will be restored almost immediately to normal, and the incision will have healed by the end of twenty-four hours in the vast majority of cases.

Acute suppuration of the middle ear, the cause of the earaches with which we are so familiar, presents an entirely different clinical aspect. The patient has almost

\* Read before the Essex North District Medical Society, Jan. 1, 1902.

from the first a sharp pain in the ear, steadily growing worse. Inspection of the drum shows a congestion of the upper posterior part, which gradually increases until the whole upper part of the membrane is involved. Should the disease progress still further, there will appear a decided bulging of the upper posterior quadrant, with marked deafness.

In the early stages, heat applied locally is of as much value as any one thing. A good way of using it is to douche the ear every hour or two with water as hot as can be tolerated, using from one to two quarts of fluid each time, in order to get a prolonged application. In severe cases it is well to also employ heat in the form of a hot water bottle, or hot salt bag, between the douchings. Free catharsis should be attended to, and it may be necessary to give a little bromid, or phenacetin. In mild cases this treatment will cut short an otherwise painful illness, and the patient will escape with only a few hours of pain, and subsequently a feeling of fulness with slight deafness. In the severer forms of infection the inflammation goes on rapidly to pus formation, with the consequent bulging of the drum of which we have just spoken.

Here we have arrived at a stage which often puzzles the general practitioner. He knows that he is justified in using palliative treatment to a certain extent, but he also has in mind a wholesome dread of possible infection of the mastoid, or of the meninges, even, should the case be neglected. To allow the abscess to develop until it opens spontaneously is to needlessly expose the patient to these dangers. The question then naturally arises, when shall he perform paracentesis, and also, what risk is he running by so doing?

In answer to the first I would say that whenever we have a bulging of the drum, with pain which is not easily controlled by the means we have mentioned, I should unhesitatingly open the membrane. In doing this the whole posterior half of the drum should be freely incised, a curved opening being preferable, as not so likely to close again too quickly. Regarding the dangers of this procedure, they refer mostly to the future hearing of the patient. Until one has had a little experience, there is, of course, some likelihood of injuring the delicate mechanism of the middle ear, but hearing is of secondary importance as compared with bringing the patient safely out of the trouble. In practiced hands no evil result need be feared, as most of these cases recover their normal degree of hearing. The operation is an exceedingly painful one, and is best done under the influence of primary anesthesia. We must not expect the escape of a large quantity of pus immediately on opening the drum. There is usually a free bleeding at first, followed by a serous discharge for twelve or more hours, before we get pus. As has been repeatedly proven by cultures, the bacteria are there from the start, but have not sufficient opportunity to multiply. To minimize this growth of bacteria, and to prevent the access of others from without, it is better before doing paracentesis to carefully cleanse the canal with a cotton stick dipped in an antiseptic, and then to allow a corrosive sublimate solution of a strength of 1 to 5000 to remain in the ear for at least five minutes. The paracentesis needle is, of course, sterilized, and after the bleeding has in a measure subsided, the canal is carefully cleared of blood clots, and a loose wick of sterilized absorbent cotton inserted. Outside of this, still another piece of cotton is placed, for the purpose of receiving the capillary drainage of the wick. This latter piece is to be changed as often as it becomes soiled, the wick remaining

in place for twenty-four hours, when it is replaced by a fresh one. Wicking is kept up as long as the discharge is thin enough to escape through the cotton. By means of this method of treatment we materially reduce the risk of infection from without, as must inevitably result when we syringe the ear, and in a certain proportion of cases the ear will cease to discharge after one or two days, healing without having really suppured.

When an ear is really suppurating actively, however, we have to resort to the use of the syringe as a measure of cleanliness. It is best used in the form of a douche, the heat being grateful to the patient, and tending to allay the inflammation. Leeches are sometimes of value where the congestion is very great. They are best applied immediately in front of the ear, and over the mastoid process. It is absolutely essential that the opening in the drum should be maintained during the progress of the disease, and this sometimes requires repeated openings.

It sometimes happens that the patient does not come to us for treatment until after the most severe of the inflammatory symptoms have subsided. He may complain simply of deafness, or of the inconvenience of having a constant discharge from the ear. Examination after cleansing the canal of all secretion will usually show a red and edematous drum in which we may possibly see the perforation, or the latter may be so small as to be invisible except on performing Valsalvan inflation. When this is done, fluid or air will come out through the drum, making the location of the hole apparent. If we keep the canal cleared of the purulent discharge, the natural tendency in acute cases is toward recovery. Keeping in mind the fact that our abscess cavity is inside the drum, and that the perforation may be so small as to be invisible, we can readily see the futility of attempting to bring about a cure by instilling the various solutions recommended for this trouble. It is probable that not one particle ever enters the tympanic cavity. Of course, this does not apply to cases with larger perforations, but these do not usually appear in acute cases, and to discuss them would be to open up a larger field than we have time for to-day. When the discharge is profuse it is my custom to have the patient syringe the ear several times daily, allow it to dry as well as possible, and then blow in a small quantity of boracic acid. As the discharge diminishes, it is sometimes preferable to use the so-called dry treatment, mopping out the canal with a cotton stick, and then using the powder. We should keep track of the hearing during this time, for cessation of the discharge alone might mean that the drum was closing prematurely, to cause mischief later on, but a diminished discharge with improved hearing would indicate recovery.

A point of great interest to the general practitioner is the recognition of the presence of infection of the mastoid. Many times I have had the statement made to me by physicians that they have been in practice twenty years, we will say, and have never seen a case of mastoiditis, and almost in the next breath ask: What are the symptoms?

Here we have the whole matter in a nutshell. It is not that the disease is infrequent, but because the symptoms are obscure, and in many cases to be made out only by inspection of the ear by means of the speculum and reflecting mirror, that it is not more often detected. Because some years since mastoid abscesses were not commonly opened until there was an exudate of pus between the bone and periosteum, this is the picture most often before the minds of many of us at the mention of the

disease. We rather expect to see a certain amount of edema behind the ear, and perhaps fluctuation.

Fortunately for our patients, we are to-day enabled to detect the presence of extension to the mastoid long before it has reached this stage. Every patient who has an acute suppuration of the middle ear should be carefully examined for evidences of mastoid involvement, as symptoms may appear as early as the second day. It is a well-known clinical fact that the absence of temperature is no guide whatever; during the acute process in the middle ear we are apt to have some elevation, but this may entirely subside with free discharge from the ear, even although the mastoid be filled with pus.

Tenderness over the mastoid antrum is apt to be a better guide, but it must be remembered that this is often apparent only on deep pressure, and also that with some very thick bones we are not able to elicit tenderness.

In the absence of these two symptoms we are obliged to turn to an inspection of the condition of the middle ear. With an increasing collection of pus in the mastoid there will be a more pronounced bulging of the drum, and in many cases which give no evidence externally there will be almost a complete closure of the auditory canal from swelling of the wall nearest the mastoid. There is usually much pain with this condition, but in some cases, and especially with phthisical patients, there is none. The presence of this increased swelling of the drum and posterior canal wall is diagnostic of mastoid trouble, however, and it should not be allowed to persist long without operation.

Now as to the treatment which should be instituted once we have made the diagnosis. We must bear in mind the fact that mastoiditis is always secondary to a purulent inflammation of the middle ear, and use our best efforts to abort this trouble. Free drainage should be maintained through the drum, and at the first suspicion of tenderness or other sign of mastoid involvement we should apply cold by means of Leiter's coil. At this stage leeches to the mastoid are often of value, and the patient should, of course, be kept in bed. Active treatment should at the same time be continued for the suppuration in the middle ear, as we have just indicated. If the pain and tenderness of the mastoid persist for more than twenty-four hours after free paracentesis and the use of the cold, it would be advisable for most practitioners to consult with some one skilled in such matters, as there is very great danger in delaying operation too long. No one can tell in which direction the pus will turn to seek relief, and practically the only notice we have of its penetration inwards to the lateral sinns or brain is a sharp chill, ushering in a condition of septicaemia, and then it may be too late to interfere.

Carried out in competent hands the mastoid operation is devoid of danger, and in uncomplicated cases the patients recover so rapidly that it is often advisable rather than submit to the tedious processes of spontaneous recovery, which may take many weeks, and which gives us no assurance that the patient may not ultimately be obliged to submit to operation after weeks of delay.

**Prescribing by Druggists.**—The Paris "Syndicat des Medecins" sued a pharmacist for illegal practice of medicine because he had made an analysis of the urine of an applicant and then prescribed for him on the ground of what he found in the urine. The court decided that pharmacists are not competent to draw conclusions from examination of the urine so as to prescribe understandingly, and consequently condemned the defendant to a fine of \$10 and a similar sum to be paid to the syndicate.

## AN IMPROVED METHOD OF EXAMINING THE FEMALE BLADDER.

J. CLARENCE WEBSTER, M.D.

Professor of Obstetrics and Gynecology, Rush Medical College, the University of Chicago.  
CHICAGO.

In his earlier papers describing his method of examining the female bladder, Dr. Howard Kelly recommended that the necessary elevation of the pelvis be obtained by placing pillows under the hips as the patient lay on a flat table in the lithotomy position. More re-

Fig. 1.—Boldt table representing the elevation used in examining the female bladder. The author's shoulder support is shown, attached to the table top. The leg holders are also in position.

cently he has advocated the genupectoral posture as more advantageous.

Each of these methods has certain disadvantages. When the first posture is adopted, the examination is frequently unsatisfactory. The elevation necessarily leads to a flexing of the upper part of the abdomen on itself. This interferes with the free descent of the intestines toward the diaphragm, which is necessary to the complete distension of the bladder with air. The hips can not be raised much above twelve or fourteen inches without discomfort to the patient if she be not anesthetized, and if an anesthetic be employed, the cramping of the abdomen interferes with free respiration. In women with tense or fat abdominal walls, it is often impossible to obtain distension of the bladder by this method.

The genupectoral posture, while undoubtedly most

favorable to bladder distension, is very unpleasant to the patient if she be not anesthetized, while if an anesthetic is used, its administration is very awkwardly carried out. The patient's neck is apt to get much bent, and if she vomits or secretes mucus freely there is often trouble in managing these complications satisfactorily. Moreover, the position of the examiner is not apt to be at all a comfortable one, especially in catheterizing the ureters.

During the past three years the writer has employed a method which is free from these objections. The patient is placed on a Boldt operating table in the lithotomy position, the ankles being fastened to upright rods, the buttocks projecting slightly over the end of the table resting on a rubber pad. A steel bar with two padded supports is attached to the top of the table so as to support the shoulders. After the external genitals and vagina are cleansed, the patient is enveloped in sterile sheets, the urine is withdrawn from the bladder, the

This posture has all the advantages of the genupectoral position and none of its disadvantages. In difficult cases in which distension of the bladder has not been thoroughly satisfactory I have not been able to get better results by trying the genupectoral position. This method is also advantageous in the cases in which examination of the bladder or catheterization of the ureters is to be followed by operation. The table is merely lowered and the procedure at once begun if the vaginal route is to be chosen.

In the examination of the rectum also, the position is highly satisfactory, air distension being obtained in the great majority of cases as soon as the anus is opened. The various forms of rectal specula may be used with great ease. I have also found it serviceable for certain obstetric maneuvers for which the genupectoral position has hitherto been employed.

## THE DIFFERENTIAL DIAGNOSIS OF TYPHOID FEVER.\*

WILLSON O. BRIDGES, M.D.

Professor of Medicine, University of Nebraska College of Medicine, OMAHA, NEB.

The combined group of symptoms which establishes the diagnosis of typhoid fever are: a gradually increasing fever with evening exacerbation and morning remission; general malaise with headache; a furred tongue with red edges and tip; nose bleed; a relatively slow pulse (possibly dicrotic); abdominal distension with tympany, gurgling and tenderness in the right iliac fossa on firm pressure; a roseolar eruption confined principally to the abdomen and chest; enlarged spleen, and the physical signs of bronchial catarrh.

Should every case of typhoid fever present the foregoing symptoms, the diagnosis would be simple and mistakes would not be common, but unfortunately this is not true and I believe the classical history, as portrayed in the books, is the exception rather than the rule. Because of the great variability in the symptoms and the tardiness of the appearance of many of them, the diagnosis is often not clear until the patient is far advanced in his illness. We have to wait a week from the commencement of the attack to demonstrate the characteristic fever chart, seven to ten days to find the rose spots, usually the same time to demonstrate an enlarged spleen; during this period what an anxious time the attending physician has in satisfying the family and friends that he is positive as to the nature of the trouble. Too often he starts off with la grippe, which does not respond in a few days to treatment, but turns out to be a malarial fever which later becomes complicated by typhoid at the first sign of an intestinal hemorrhage or a perforation.

Probably typhoid fever can be made to answer for a greater number of affections than any other disease. The only consolation the physician can find in his unfortunate position frequently is, that he is not the only one to be similarly situated; in fact, he is not even an exception, for we have all been there and will be again. The eminent men who were in attendance upon the Czar of Russia a year ago had him down with la grippe for nearly a week before typhoid fever showed up.

In quite a number of cases, the preponderance of some symptom leads away from the suspicion of the disease, and accounts for many errors in diagnosis. I have seen the physical signs of bronchitis so intense in the early

Fig. 2.—Method of examining the female bladder on the Boldt table.

urethra is dilated to the necessary size and a speculum containing its obturator introduced into the urethra. By means of a crank the top of the table is turned on a transverse axis so that the lower end is elevated and the upper end depressed. The patient is thus made to rest on an inclined plane, being held by the shoulder supports, her trunk being flat against the table and not bent in any way, so that her respiration is free and the anesthetic easily administered. The writer usually raises the table-top until its lower end is twenty-three inches above the normal level. The obturator is then removed from the speculum, allowing air to enter and dilate the bladder. The examination of the bladder and ureters is then carried out, the examiner standing on a stool so that the eyes may be well above the outer end of the speculum.

\* Read before the Potra Valley Medical Society, at Avoca, Iowa, Feb. 13, 1902.

history of a case with accompanying high fever as to entirely mislead: the pain in the head so great as to make the attending physician certain of a case of meningitis, and obstinate constipation with distension and tenderness in the right iliac region are suggestive of appendicitis; and I have myself a number of times, from the rapid onset and severity of chilliness, headache, general aching, fever and cough with acute catarrh of the whole respiratory tract, felt certain of a diagnosis of la grippe, only to find out later that I had guessed too soon. There seems no similarity whatever between a so-called walking case of typhoid fever and a case presenting most all the characteristic symptoms in their greatest severity, and within these two extremes what can not be represented? The physician who does not make snap diagnoses, or, properly speaking, "guesses": who examines every case of disease carefully at each visit; who elicits a clear, concise history and always has typhoid fever in his mind when he finds a continued fever, will come out in the long run with fewer mistakes charged against him. It is not that we are not conversant with the diagnostic symptoms and signs of typhoid fever, but it is that we do not sufficiently apply that knowledge to the individual case.

It is important that the diagnosis be made at the earliest possible time, and yet this is not always practicable because of the tardiness of many prominent diagnostic symptoms. Fortunately for him, the physician is not consulted until the patient has ailed for several days, and the history will be presented of a slowly-developing affection which will be in marked contrast with most other acute diseases. I have come to regard a relatively slow pulse, which is so often present throughout the entire course of the disease, as strongly suggestive of typhoid and if it be found dicrotic in character the presumption will be quite strong. This is also in marked contrast to most diseases confounded with typhoid fever. The pulse in the first week rarely exceeds 90, is often 80 or less, even in the presence of a temperature of 103 or more. Women and children are frequent exceptions to this rule.

An early sign almost invariably present is the diazo-benzol urinary reaction of Ehrlich, which is commonly found as early as the fourth day. A few years ago the writer read a paper before the Missouri Valley Medical Society on the "Early Diagnosis of Typhoid Fever," in which his experience with this test, as applied to about 20 cases, was narrated, and his observations since, extending over about as many more, confirm his belief that the application of this test is not sufficiently frequent in practice, and that its value as a diagnostic sign is underestimated. The very fact that it may often be found by the fourth day, three days before the earliest rose spot, or palpable spleen, adds to its importance. True, it is found in malaria, in measles, in the latter stages of tuberculosis and in smallpox; but aside from malaria, these affections could hardly be confounded with typhoid fever. There is response to the test until about the eighteenth day of the fever. On the occurrence of a true relapse it reappears. I always keep the solutions on hand and have found it advantageous to carry them with me to suspected cases in the country. The test solutions are: 1. Sulphanilic acid, grains 20; hydrochloric acid, drams 3; distilled water, ounces 8; mix. 2. Sodium nitrite, grains 24; distilled water, ounce 1. 3. Aqua ammonia. 2 drams of No. 1, are mixed with 3 drops of No. 2 in a test tube; an equal quantity of the urine added and thoroughly shaken.

Eight drops of ammonia are then allowed to fall upon the foam, when a distinctly pink color of the latter occurs, to be followed by a bright carmine-red zone underneath. If the liquid be then poured into a white porcelain dish it will appear as a light yellowish red.

The Widal blood reaction is of considerable diagnostic importance, and when obtained in dilutions of forty or more, the certainty of the existence of typhoid fever in a suspected case may be entertained. Work along this line is demonstrating, however, that the reaction occurs in those who have previously had the disease, and this fact should be elicited before the deduction is made. It requires fresh cultures of the bacillus typhosus to make the test satisfactorily, and hence it is not always practicable to the country practitioner.

In cases where the test is essential to clear up an uncertainty, a coverslip of blood or serum can be readily sent to the bacteriological laboratory connected with any of our medical colleges. The typical reaction does not usually occur before the sixth or seventh day; exceptionally it is considerably later.

The rose spots vary within wide limits as to numbers and location. Oftentimes they are so few as to escape detection unless carefully searched for. Their diagnostic significance is based upon their disappearance under pressure, to reappear so soon as the pressure is withdrawn: their non-elevation above the surface, and the individual spot having a life history of three days. They are occasionally found upon the arms and about the wrist. I believe from my own observation that they may be found in every case. Not appearing before the seventh day and occasionally as late as the tenth, they are of course not an early diagnostic sign.

The combined symptoms which are almost invariably present during the first week to be relied upon for a presumptive diagnosis are: a daily increasing temperature with headache and malaise; moist furred tongue with red edges and tip; a pulse of 80 or thereabouts and evidences of bronchial catarrh. If to these be added the diazo-benzol urinary reaction on the fourth to the sixth day with or without the occurrence of nose bleed, the presumption is very strong. A palpable spleen, rose spots and the Widal reaction early in the second week, supplementary to the foregoing, would make the diagnosis absolute.

The diseases most commonly mistaken for typhoid fever are: remittent malarial fever, continued fever of uncertain septic origin, commonly called simple febricula, acute miliary tuberculosis, la grippe, appendicitis, typhoid pneumonia, and septicemia.

Remittent fever or estivo-autumnal fever is the only form of continued fever of malarial origin. It is rarely seen outside of malarial districts and in this section of the country is scarcely known excepting in the arena of a mistaken diagnosis; and yet I believe more cases of typhoid are treated for malarial fever than are treated for typhoid. This is a broad statement but it is based upon observation and experience. The word malaria covers a multitude of sins, but it is inexcusable to carry it into a domain where recent knowledge and methods can so readily disarm. There are many points in common between these two fevers, but there are more points of difference. Malarial fever is usually ushered in by a distinct chill, often repeated, followed soon by high fever with two daily exacerbations and remissions; typhoid by chilliness followed by gradual rise in fever with only one exacerbation and remission daily. The rapid pulse of commencing malaria is in marked con-

trast with the slow pulse of typhoid. In the former there is rarely nose bleed, in the latter this is quite frequent. There are rarely abdominal symptoms in malaria, and there is commonly nausea and vomiting. The roseola is not found in malaria. The presence of the Widal blood reaction would be favorable to typhoid, and the crescentic plasmodium in the blood demonstrable by the microscope would be positive of malaria. An intestinal hemorrhage would be presumptive of typhoid and a marked susceptibility of the fever to quinin would savor of malaria. Simple febricula has not the nose bleed, slow pulse, diazo urinary reaction, palpable spleen, roseola and abdominal symptoms of typhoid; runs a shorter course and is much more readily influenced by treatment.

Acute miliary tuberculosis has not infrequently been confounded with typhoid fever. The onset of the former is more rapid and pronounced, the pulse rate much higher, greater frequency of respiration; there is not apt to be nose bleed, palpable spleen, rose spots; there is decided tendency to fine moist râles throughout the chest with loose cough not common to typhoid, and frequently the sputum will contain abundance of tubercle bacilli.

La grippe and typhoid fever prevail at the same season of the year. Mild cases of the latter are not unlike moderately severe cases of the former which have not early complications. La grippe is more sudden in onset, is usually consecutive to or coincident with a cold, has a more rapid pulse, the fever is more susceptible to treatment responding in two or three days where sequelæ do not supervene; the diazo-reaction is absent, and there are no rose spots or palpable spleen.

Cases of prolonged appendicitis with slow onset will present differences only which require close investigation. The pulse here will be higher in proportion than the fever, the morning and evening temperature will vary less; there is no nose bleed, or roseola, or enlarged spleen, or bronchial catarrh, or diazo-reaction. There is more apt to be abdominal pains, muscular rigidity in right iliac region and moderate leucocytosis, which is much increased where pus is present.

Walking cases of typhoid with perforation of the intestine, are quite suggestive of fulminating appendicitis, and I have known errors of diagnosis to occur where, at operation, a perforated intestine and ulcerated Peyer's patches demonstrated the typhoidal character of the case. Intestinal perforation occurs at such a time in typhoid fever that a careful inquiry into the above differences in the symptoms and signs should leave no room for doubt, and although operation might be advisable in both, it is much the more satisfactory that the diagnosis be made beforehand. Appendicitis may complicate typhoid fever and develop when the abdominal symptoms are most pronounced. A case of this kind was reported to the American Medical Association at the meeting in Atlantic City by Dr. Siegfried Weiss of Vienna, reported in *THE JOURNAL* of Nov. 24, 1900. The case was that of a child  $9\frac{3}{4}$  years old, which was supposed first to have influenza, then typhoid; then on the development of signs of an inflammatory tumor in the appendical region, and leucocytosis, the former diagnoses were thrown over and a suppurative appendicitis accepted. Why the author discarded typhoid I can not understand, for the symptomatology included fever, bronchial catarrh, diazo-urinary reaction, enlarged spleen, rose spots, diarrhea and the Widal blood reaction with the development of the local signs of

appendicitis only on the twelfth day of the illness. Was it not more likely a typhoid infection with involvement of the appendix? Why this complication is not more common puzzles us, for certainly the bacillus typhosus should have as ready access to the appendix as do foreign bodies, which enter from the intestine to excite inflammation. Perhaps it is more frequent than we think for, but undetected.

Typhoid pneumonia is a misnomer, for it suggests the presence of a typhoid infection in a type of pneumonia which is so severe as to present certain symptoms suggestive of the typhoid state, when in reality the latter does not exist. The disease starts in violently with severe chill, high fever, rapid pulse, pain in chest, frequent breathing, to be soon followed by low delirium, abdominal distension, involuntary evacuations, coma and death within a week or so. The frequent absence of cough and expectoration mislead. A careful examination of the chest will detect a solidified lung, and a marked leucocytosis will indicate no typhoid fever.

Septicemia of gradual onset presents a similarity of symptoms which lead to error, and especially when typhoid occurs in the puerperal state. In septicemia there is usually discoverable some focus of infection; it is attended by a higher relative pulse-rate; there is not the fever chart of typhoid. Frequently sweating occurs, the rose spots are absent as is also the Widal blood reaction.

The irregularity of typhoid fever in children, I believe, accounts for its supposed relative infrequency at this period of life. In many cases the onset is more abrupt; there is less apt to be complaint of general malaise; nose bleed is comparatively rare; nervous symptoms are more pronounced. The abdominal symptoms, when present, are similar to those of enteric or gastro-enteric catarrh and especially in young children or infants are many of the symptoms wanting.

If the diazo-urinary test, and the Widal blood reaction and splenic enlargement and a search about the abdomen and chest for rose spots, were more carefully inquired into, in the continued fever of early life, we would find more typhoid. The loose movements of enteric catarrh are not like those of typhoid. They are apt to be green; they contain mucus, sometimes blood and generally undigested food. Colicky pains frequently precede or attend the movements, all of which are not found in typhoid fever.

#### GRAVE ABDOMINAL INJURIES WITHOUT EXTERNAL EVIDENCES OF TRAUMATISM.\*

R. HARVEY REED, M.D.

Professor Emeritus of Principles and Practice of Surgery and Clinical Surgery, Ohio Medical University; Division Surgeon, U.P.R.R. Co.; Surgeon U. S. Coal Co.; Surgeon-General of Wyoming.  
ROCK SPRINGS, WYO.

It has been my privilege during the last twenty years to have met with a class of grave abdominal injuries which has given little or no external evidences of traumatism. The patient in each instance has given a history of a severe injury which resulted in death in from 24 hours to 26 days after the traumatism. I will only report three of these cases in detail, as the others were practically duplicates and to make a full report would only take up valuable time without special advantage.

The first of these cases which came to my notice oc-

\* Read before the Western Surgical and Gynecological Association, at Chicago, Dec. 18-19, 1901.

curring about fifteen years ago, in an unusually large, healthy man of some 36 years of age, who had charge of a planing mill in Crestline, Ohio. At the time the accident occurred, he was engaged in sawing palings with a buzz-saw. These palings were about three feet in length, some two inches wide and one inch thick. In some manner one of them caught in the buzz-saw, and was thrown forcibly endwise, a distance of some six feet, striking him very forcibly over the left hypochondriac region. Whilst the injury caused some pain, he continued his work for a short time, when he became sick and was taken to his home. Two of the local physicians were called in to see him, and being unable to find any external signs of injury, further than the mark made by the end of the paling, which had simply reddened the skin for a distance of two inches in one direction and one inch in the other, they were of the opinion that he was simply suffering from shock and that he would soon recover. On the contrary, he continued to grow worse; the abdomen became tympanitic and grave symptoms made their appearance. I was called in counsel, and, after examining the case carefully, gave it as my opinion that there was a rupture of the intestine and advised operation. There being no hospital at our command and not even trained nurses, he was operated on at his home with the assistance of the local physicians. On opening the abdominal cavity, I found the abdominal parietes perfectly intact. Not the slightest ecchymosis or the slightest tear of the muscles of the abdominal walls could be found. On entering the abdomen, I found a large tear of the ileum, located immediately under the point of contact made by the paling. This tear was of a triangular nature, and was sufficiently large to enable me to pass my finger into the intestine through this opening without difficulty. The abdominal cavity was filled with fecal matter. Acute general peritonitis had set in, and although the abdominal cavity was washed out carefully and the injured intestine sutured with silk, the patient died in three days after the operation, about six days after the injury. It seemed to me at the time remarkable that a traumatism of this character should produce such a grave injury of the intestine without injury to the abdominal walls, further than a little reddening of the skin.

A few years later, I saw in counsel two cases similar to the one above described. One was kicked by a horse and the other, while running at night, ran against the end of a rail. In each instance there was no injury to the abdominal walls, but a tear of the stomach in one case and of the large intestine in the other, produced death a few hours after the accident. I regret that I have not all of the details of these two cases at my command, yet at the same time they are so nearly like the one already described that it would add but little to our fund of knowledge if we were able to give the full details of them.

On Sept. 21, 1901, a Bohemian miner, aged 45, was caught by falling rock, producing a contusion of the back and hips, extending to both thighs, without fracture of the pelvis. He was brought immediately after the injury to the Wyoming General Hospital, which was less than two miles from where the accident occurred, and was admitted to the same as Case No. 1816. He suffered severely from shock, which was complicated by vomiting and epistaxis, but beyond this, no hemorrhage occurred. The ordinary line of treatment was followed, such as morphin and strychnin for the shock, with warm local applications over the contused parts. He

never rallied from the shock and died in about 24 hours after the accident. A postmortem, held 12 hours after death, revealed two perforations of the small intestine, located about six inches above the ileo-cecal valve, which were followed by peritonitis, the result of infection from the fecal extravasation. A careful examination failed to find any material injury to the abdominal walls, not even a tear of the parietal peritoneum, and no solution of continuity of any of the muscular layers of the abdominal walls. In fact, the injury had not produced any marked ecchymosis, and the physical signs usually present in severe injuries were conspicuously absent.

A similar case to the one I have just described was admitted to the Wyoming General Hospital, Nov. 20, 1901, as Case No. 1895. This man was an American, aged 30; occupation, a driver in the Union Pacific Coal Company mine at Spring Valley, Wyo., and was injured Nov. 15, 1901. While driving the cars, he was caught in some way between the "ribs" of the mine and car, sustaining a contusion on the left side and back, with a fracture of the pelvis on the left side, along the ileo-ischiatic juncture. There was no evidence of displacement of the fragments, but in certain positions, crepitus could be readily elicited. The symptoms were so negative at first, that the very competent assistant surgeon, Dr. Levers, was led to believe that the injuries were of a trivial character. During the first four days following the injury, the patient's pulse, temperature and respiration was normal. Following the administration of small doses of magnesium sulphate, he had thorough evacuation of the bowels. Notwithstanding the fracture of the pelvis, this man was able to be up and stood on his feet and walked some on the third day following the injury. On the morning of the fifth day, his condition suddenly grew worse, pulse increased to 120 and temperature decreased to 97. The abdomen became distended, was dull on percussion over the left side and the patient became delirious, in which condition he reached the Wyoming General Hospital, on November 20, five days after the accident.

The general appearance of this case when he reached the hospital was such as to impress one with the fact of the existence of a rupture of the intestine, with localized peritonitis, except for the fact that his bowels moved regularly, which could hardly be expected in case of a rupture, with either general or local peritonitis. His delirium continued for four or five days after his admission to the hospital, when it began to subside, and his temperature, which had ranged from 98 to 103.5, subsided to normal, although the dullness over the left hypochondriac region continued. This, however, began to subside, until the resonance on the left side of the abdomen approached nearly to the normal, which led me to the conclusion that we had had a hematoma to contend with, which in my judgment was located between the layers of the muscles of the left side of the abdomen.

About December 3 the patient became worse. The area of dullness suddenly became much larger and very marked. His temperature ranged from 97 to 103.5 F., and an operation seemed to be imperative. I operated on this case on December 6, making an incision in the left iliac region. I dissected carefully through the different layers of muscles, and to my surprise, found them intact, and no hematoma. On passing through the last layer, I found a large cavity, filled with blood, broken-down blood clots, and serum. This cavity contained about a gallon of this liquid. After washing the cavity out thoroughly, I found that the peritoneum had been

tern loose from the walls of the abdomen from a point midway down the pelvis to the diaphragm, and from the rectus muscle anteriorly to the vertebra posteriorly. The left kidney had been displaced and was apparently floating, and the entire descending colon, together with the balance of the abdominal viscera which should occupy the left side, were pushed over to nearly the median line, and were enveloped in a sack of loose peritoneum. There was not the slightest evidence of peritonitis, the bowels being flat, and apparently showing no signs of irritation.

There being considerable hemorrhage in the form of capillary oozing, I carried a second incision at right angles with the first, for the purpose of drainage, cutting through the abdominal muscles, to the outer border of the lumbar muscles. After thoroughly cleansing this cavity, I drenched the parts with hydrogen peroxid, after which it was packed with a large quantity of gauze soaked in warm bichlorid evaporating solution. The patient, although weak and exhausted before the operation, rallied from it very nicely.

The day following the operation he seemed to be semi-conscious, which seemed to be the result of exhaustion, as there was no evidence of inflammatory trouble, and little or no rise of temperature. There was no effort at repair, and whilst the wound remained perfectly clean, there was a peculiar ammoniacal odor connected with it, although there was no evidence of escape of urine into the wound from either the kidney, ureter or bladder; this condition, to my mind, indicated molecular dissolution. There was incontinence of urine, and whilst the patient took considerable nourishment, which apparently seemed to digest, yet he gradually sank and died on December 11, just five days after the operation and twenty-seven days after the accident.

#### GENERAL COMMENTS.

We have had here a series of injuries in which there were grave abdominal injuries without corresponding external evidences of traumatism, yet the result in each case was fatal. In four of the cases reported, we have had rupture of some part of the alimentary canal, followed by death. What are the lessons we are to learn from these grave accidents? Could the lives of these patients have been saved through operative interference?

In the first case, in which the patient was struck by a piling, I firmly believe that if operative interference had been resorted to immediately after the accident, that the patient would have survived the injury. In the case of rupture of the stomach, there was such general infection of the entire abdominal cavity, as shown by the postmortem, such rapid collapse, that I question whether it would have been possible to have saved the life of this patient unless the surgeon had been actually on the ground at the time, and made immediate operation. It must be remembered, as in this case, that these accidents frequently occur miles from surgical aid, and by the time the surgeon reaches the patient the time for active interference has past.

This applies to the third case, in which the patient ran violently against the end of a rail, producing rupture of the intestine, but as the patient was past all hope of recovery when seen by the writer, and no postmortem was permitted, it is only conjecture as to the real injury produced. At all events, operative interference would have failed in this case by the time it was possible for a surgeon to reach him.

In the Bohemian miner, the question of immediate operative interference might well be considered. This man

was in the hospital in less than three hours from the time the accident occurred. The question of operative intervention came up, but inasmuch as the patient never rallied from shock, I do not consider it good surgery to undertake an abdominal operation without any knowledge of where the injury might be located, with a pulseless patient, suffering from extreme shock, from which he never rallied. Had I seen the slightest sign of rallying, I would have operated on him at once.

This, of course, brings up the mooted question of operating in shock, and although I have for many years advocated major amputations under shock, and have made many such amputations under such circumstances where the patient has rallied after the removal of a mangled limb, which I doubt ever would have rallied without its removal, I was skeptical in this case. In abdominal operations where there is severe shock, it seems to me that there is a different condition of affairs to contend with, and it is a question in my mind whether operative interference for grave abdominal injuries, with the patient suffering from the severest form of shock, is advisable, or would result in benefit to the patient except in hemorrhage.

The last case is a peculiar one, and brings up the question of operations for hematoma. It is my custom not to operate for hematoma as long as there is reasonable hope that they are being absorbed. I see many accidents every year in which there are severe hematoma located between the muscles, which are rapidly absorbed, and the patient gets well with little or no difficulty. Occasionally we have hematoma that do not absorb, which I consider proper cases for operative interference, and would treat such cases the same as I would a pocket of pus: evacuate and drain thoroughly. We admit, in these days of antiseptic and aseptic surgery, that incision into muscular tissue with evacuation of collections of blood, ought not to be followed by infection, but notwithstanding all the precautions the surgeon may resort to, these patients are liable to become infected. I seldom make compound of simple or open or closed wounds when it can be avoided, and particularly so where nature is inclined to take care of the extravasation by the natural channels of absorption. This is particularly true when we have different nationalities to deal with who do not readily understand or thoroughly comprehend the English language and are liable to unintentionally disregard the surgeon's instructions.

#### CONCLUSION.

From reading the literature of this class of cases, together with my own experience, I am led to the conclusion that it is the surgeon's duty to make an exploratory incision in all cases where there is grave doubt as to the real nature of the injury, and particularly so when the constitutional symptoms point to a condition more serious than is indicated by either the subjective or objective symptoms, provided the physical condition of the patient is such as to warrant an operative procedure.

### Clinical Report.

#### UNPRECEDENTED CASE OF CONSTIPATION.

D. GEIB, M.D., AND J. D. JONES, M.D.

GROTON, S. D.

This case, reported to the South Dakota State Medical Society, June, 1900, and to the Aberdeen District Medical Society, June, 1901, by Dr. D. Geib, was further described in a communication to the Aberdeen District Medical Society, September, 1901, by Dr. J. D. Jones and concluded by report

of the ease to time of death, January 8, 1902, with autopsy, by Drs. O. Geib and J. D. Jones.

The patient, Mr. K., having enjoyed good health previous to the age of 11, began at that time to be constipated and was treated for three months by Dr. Nicholas Senn, then of Dodge County, Wisconsin, no bowel movement being secured. The only result of cathartics and laxatives was severe pain. The constipation continued until death. It was a common occurrence for him to go three weeks or as many months without a movement of the bowels. At the age of 20 he did not have a movement for three or four months at a time. He consulted a homeopathic physician, who prescribed for him two drops of croton oil, to be doubled in two hours, tripled in four hours, and quadrupled in six hours. This produced no result but after a period of several weeks, his bowels moved again.

For seven years following, his bowels were fairly regular. At the age of 29 he contracted a severe cold and five months and three days passed without an evacuation. After a few months of regularity, his bowels did not move for six months and fourteen days. At this time he consulted Dr. Stamm of St. Paul, without immediate benefit, but during the next six years his bowels were regular. In February, 1900, the constipation returned. The patient had no movement from June 18, 1900, to June 21, 1901.

During these periods of costiveness he could eat full meals and do a good day's work. His respiration was always normal; the urine was normal when he was free from pain, but

about two pounds of the feces could be removed before the patient complained of pain; his weakened condition prevented further operation. The circumference of the patient at this time at the ensiform cartilage was 39 in., at the umbilicus, 38.5 in., and at the crest of the ileum, 39 in.

On arrival at the house on the morning of June 22, the report was received that he had passed an ordinary paillful of feces since the day previous. There was much rejoicing in the family. The patient was very weak and sore, so no further operation was attempted at this time, but the olive oil enemas were ordered continued.

The patient, when next seen, on June 25, was feeling comfortable; the gas had ceased to trouble him and he had passed about three quarts of feces that morning. His measurements at this date were, at the ensiform cartilage 34 in., umbilicus 33 in., and at the crest of ileum 30 in.

The enemas were ordered continued. Mr. K. estimated that he had passed about eight gallons of feces since the beginning of the treatment. On June 29, he was cheerful and pleased at his progress. The measurements at the ensiform cartilage were 34 in., umbilicus 30 in., crest of ileum 29 in. From that date he received massage treatment given by Dr. Geib, twice a week for three weeks, and improved in strength so that he was able to ride to town and walk about. One July 8, after his massage, he suffered considerable pain for about three days.

His bowels moved frequently. The contents were described as resembling soft soap and during this period of discomfort he passed a hard mass about the size of a duck's egg, containing grape seeds. He had not eaten grapes since the fall before. After this he had little trouble and gained in strength and weight. The only treatment then given was massage, iron and strychnia.

The history of the case subsequent to the above report to the Aberdeen District Medical Society is as follows: Since the treatment in June, 1901, the bowels moved regularly; occasionally he was obliged to take an enema, but he was well nourished and weighed more than he had for years. He was very sensitive to cold this winter, chilling on the least exposure.

On the second day before his death, which occurred Jan. 8, 1902, he rode to town, a distance of eight miles. He retired at 11 p. m. apparently as well as usual, and awoke about 5 a. m. with pain. He arose about 8 a. m., built the fires and did part of his morning's work. The pain, however, became very intense and he went to the house and suffered more or less all day. There was a great desire to evacuate the bowels but it was impossible. At 2 o'clock the following morning, he died while sitting on the stool. No medical aid was called.

The autopsy showed the abdomen greatly distended with gas and fecal matter. On making an incision along the linea alba, the tension was sufficient to tear the flesh apart; the omentum was very thin and the colon was brought at once into view. The position of the colon was as shown in the photograph, save that the extra loop overlaid the normal colon. The splenic flexure, transverse colon and descending portion of the extra loop were very much thickened, containing much more muscular fiber than normal. The parts most distended were the splenic flexure, the transverse and the descending portion of the extra loop, but the whole colon was much larger than normal.

The most distended portion measured 19½ inches in circumference. The rectum contained a hard mass of feces shaped like a goose egg, measuring about 1 inches in the shortest diameter and 6 in its longest. This was pressed tightly against the splineter and acted as a valve. The remaining portion of the colon contained soft feces; the total contents were an ordinary bucketful. The stomach and small intestines were empty. The diaphragm was crowded up to the level of the fourth rib on the right side; the heart and lungs were both displaced.

**Iodoform Odor.**—Oil of turpentine is suggested for the removal of the odor of iodoform. It is claimed that it at once removes the objectionable smell from the hands or implements.

*Med. Fortnightly.*

The colon of Mr. K.

highly colored when in pain. The evacuation of his bowels made him very weak and he was greatly troubled with gas so that he had to lie on his right side to relieve himself and was partially disabled for work.

His abdomen was greatly distended so that the liver and the stomach crowded up the diaphragm and the floating ribs were visibly pushed out. There was tenderness in the sigmoid flexure, but over the remainder of the abdomen he could bear heavy pressure.

He was not troubled with gas when regular. The administration of valerian, sennal and asafetida by Dr. Geib gave him considerable relief.

On June 19, 1901, Dr. Jones was called in with Dr. Geib to relieve the patient from his painful condition. The abdomen was greatly distended. The colon, on palpation, seemed to be as large as a six-inch stovepipe. From the head of the sigmoid flexure to the rectum, the bowel seemed to be perfectly straight and hard. On digital examination the rectum was found filled with a mass of fecal matter so hard that no impression could be made on it. The anus was dilated and the mass removed from the rectum with a bone curette and hot water. Further operation was postponed because of the pain suffered by the patient, and olive oil enemas were ordered.

June 21, on further attempt to evacuate the bowels, it was found that the olive oil had softened the hard mass so that

## GLYCERINATED VERSUS DRIED VACCINE VIRUS.

During recent years glycerinated vaccine lymph has come into general use and the results obtained with it have been so favorable that the older method has been almost entirely discarded. Some doubt has recently been thrown on the relative value and advantages of dried and glycerinated lymph, and it is well to bear certain facts in mind in arriving at any conclusions. It has been shown that the vaccine material as it comes from the animal, be it pulp or exuding serum, is practically never free from bacteria. These bacteria are often non-pathogenic, but in some instances infectious organisms are present, especially pyogenic bacteria. If the lymph is stored in a moist condition without the addition of preservatives, the bacteria originally present rapidly multiply to an enormous extent and destroy the virus. If the lymph is dried upon ivory points in the usual manner, it does not part with all its moisture at once, and it is not unlikely that the bacteria in the lymph may multiply for a time. The numerous bacteriologic examinations of ivory points would seem to indicate that such is the case, as the points when they reach the market usually contain a very large number of bacteria. Rosenau<sup>1</sup> found an average of 4807 bacteria per point upon 41 dry points examined. Copeman, in 1891, devised the method of mixing the pulp or serum with pure, sterile glycerin. He found that if this were done the bacteria in the lymph gradually died, while the vaccinal organisms survived for a considerable length of time. The observations have been subsequently verified by numerous observers so that there is no doubt of their accuracy. The time required for glycerinated virus to become sterile is from two to four weeks and if the initial number of bacteria in the lymph is very large it may require a longer time or perhaps it may never occur. Rosenau examined 51 tubes and capsules of glycerinated virus, purchased in the open market, and found an average of 2865 bacteria per vaccine. It is hardly necessary to say that such a number of bacteria should not be present. Rosenau believes the impurities found in glycerinated lymph upon the market are largely due to over-confidence in the germicidal value of glycerin, operators becoming careless of contamination and trusting to the glycerin to purify their product. He also thinks that some of the glycerinated virus on the market is "green," not having been kept a sufficient length of

time before it is sold. From his studies Rosenau concludes that we ought not to discredit glycerinated virus, the superiority of which he considers demonstrated, but he condemns the practice of manufacturers who place an unripe product on the market. The general opinion of persons competent to judge is that glycerinated lymph is superior to the dried form.

In an editorial in the *New York Medical Journal* of Sept. 21, 1901, thoroughly desiccated lymph is highly advocated. The writer refers to some observations made by the late J. H. Kidder, who subjected ordinary dried vaccine slips to several days' additional desiccation by exposure in hermetically sealed receptacles to the presence of strong sulphuric acid or anhydrous calcium chlorid. Such slips were then sealed in a piece of rubber tubing and kept at 98 degrees for a month, when they were as potent as fresh lymph. Slips prepared in this way were sent as far as Japan and upon their return were found unimpaired. In discussing the papers upon vaccination read before the New York Academy of Medicine (New York *Medical Record*, March 8, 1902), Dr. Frank P. Foster stated that such desiccated lymph would keep for 7 or 8 months. It is very desirable that further observations be made with thoroughly desiccated lymph and that the fate of the bacteria contained in such lymph be determined. This method is similar to that devised by Reissner and formerly much employed with good results. The lymph was dried over sulphuric acid and reduced to a powder. The desiccation effectually prevented the growth of bacteria.

In view of the results of Rosenau's examinations, it is apparent that some measures are required to protect the public from improperly prepared vaccine virus. The lymph or pulp, before glycerin is added to it, should be so collected and protected from contamination that it will contain a minimal number of bacteria. After being mixed with glycerin it should not be placed on the market until bacteriologic examination has shown it to be sterile. Health authorities, either local or, better, governmental, should inspect the institutions which produce vaccine virus, and samples of their product should be frequently tested as to their bacterial content. When a manufacturer's virus is found contaminated beyond what is unavoidable, either because of improper preparation or from being sold too soon after collection, the facts should be announced publicly. Matters which are of such vital importance to the health of the people are not subjects to be treated carelessly nor only from the viewpoint of commercialism.

## MEDICAL EDUCATION FOR WOMEN.

Do medical schools at present supply, as well, at least, as they might supply, that psychophysical equipment, fitness of brain and hand, to women practitioners which they require to prepare them for their professional lives?

Without going far into the psychophysical nature of women as such, it will perhaps be generally granted

1. *American Medicine*, April 19, 1902, p. 637.

that women are, on the average, more emotional, more formally unreasoning, more unmechanical, physically weaker, yet stronger in sympathy, than are men. Should not these basal characteristics have far more consideration in fitting women to practice medicine than they now have? One of the strongest trends of modern pedagogy is towards the adaptation of study to the student. Boys and girls and men and women in the most successful schools no longer are treated as automata to be mechanically crammed with routine facts and systems of knowledge, but they receive the consideration really due to individuals, each of whom is unique. How much greater is the rational demand that the needs of a sex be met!

On the basis of the above-noted secondary sexual characteristics, it seems obvious that womanly women are ill adapted to be, for example, surgeons. Some things more than knowledge, experience, and a delicate touch are demanded of a surgeon, and some of these things womanly women, as compared with men, seem to lack. Minor surgery and minor gynecology are much more within the feminine sphere. Could not the average course for women medical students, with much benefit, both theoretical and practical, be better adapted in this respect?

Obstetrics one thinks of next, and here one wonders almost that the preference of women for male accouchers is so strong, a wonder that is lessened only at the thought that women consider in this perhaps the stronger judgment of men and certainly their better advantages in most medical centers for obtaining obstetric experience. Provided always that she be ready to call upon her professional brother promptly in those ever rarer cases when a surgical operation is required, obstetrics is the woman medical practitioner's best future field. Should not the medical school give her additional facilities in this direction to the exclusion, if need be, of something less well adapted to her needs?

As general practitioners women seem as well-fitted naturally as men, although perhaps lacking, relatively again, in that good and quick judgment which many a case and crisis requires. Given that confidence which future adapted medical education for the sex will inspire and a woman will be as welcome at a complex critical case as a man would be.

As children's physicians women should be the superiors of men, for they surely have an instinctive understanding of child-nature which many men sorely lack. Here again the medical curriculum can be adapted to this portion of its patrons, and can thus make women excel, to the good of the public and to the schools' additional success.

In the specialties of the ear, eye and throat women should be the equals of men naturally. But one looks in vain for the eminent female eye or ear surgeon. Women naturally have the delicacy of touch which should make them, with adequate training, the equals of their

professional brothers, provided they had the other necessary qualifications. Psychology, we know, proves that women's discriminative power and accuracy of movement are somewhat inferior to those of men. Perhaps this demonstrated fact explains all these doubts concerning feminine surgery of every sort.

These are but prominent examples of the directions in which the medical education of women may be called, from this point of view, defective or at least improvable, to-day. Whether in schools solely for women or in co-educational colleges, women are at present being taught practical branches of medicine to which they are ill-adapted, and that at the expense of time and energies which might, if better employed, be made to make women more useful both to themselves and to humanity.

However, the whole question of woman's place in medicine hinges on the fact that when a critical case demands independent action and fearless judgment, man's success depends on his virile courage, which the normal woman has not nor is expected to have.

#### THE CENTER CONTROLLING INTELLECTUAL ACTIVITY.

Localization of the intellectual functions in a definite part of the brain is a conception which though not entirely originated by Gall, the physiologist, was at least popularized and made definite through his writings. Previously, the seat of the mind or soul had been often placed in the heart, diaphragm or pineal gland. The general rejection of phrenology carried with it most of the belief in definite localization of the mental faculties. Modern psychologists generally follow Ferrier in thinking it "absurd to speak of a special seat of intellect or intelligence in the brain," and Munk who asserted that "intelligence has its seat everywhere in the cerebrum and nowhere in particular." Interest in the question has declined, especially since researches by physiologists have accomplished little except to throw them into dispute on the subject. Wundt, perhaps the foremost of physiologic psychologists, acknowledges,<sup>1</sup> however, the suggestiveness of certain anatomic findings and pathologic sequences in the cortical areas of the frontal lobe, but thinks localization of the intellectual activities in that region needs better backing through more direct evidences and through the clearing up of certain contradictory findings in cases of injury and disease.

Fulfilling Wundt's requirements by proofs which pathology more adequately than physiology can present, Phelps, who has had a large experience with brain injuries, recently publishes<sup>2</sup> his discovery that the center for control of the mental faculties is in the left pre-frontal lobe. Bearing directly or indirectly on this question Phelps has observed 800 cases of intracranial traumatism, of which more than 300 were either subjected to operation or postmortem inspection. Of these, 18 were lesions in the frontal lobes verified by necropsy.

1. *Outlines of Psychology*, p. 206.

2. *Amer. Jour. of Medical Sciences*, April, May, 1902.

For his study Phelps has also collected 51 other cases of injury to the left frontal lobe where report of intellectual condition has been given, besides including the facts in hundreds of other cases which have indirect relation to the problem. From this mass of data Phelps draws the following conclusions:

1. The more absolutely the lesion is limited to the left prefrontal lobe, the more positive and distinctive are the symptoms of mental default. 2. The integrity of the mental faculties remains unimpaired in right frontal lesion, though it involves the destruction of the entire lobe or even extends to the entire hemisphere. 3. The exceptional instances in which seemingly opposite conditions exist are always reconcilable, on more careful examination, with the assertion of an exclusive control of the mental faculties residing in the prefrontal region of the left side.

Cases may possibly arise, although Phelps has seen none, which can not be explained except by taking into account the fact that the right side of the brain, as in the well-known occasional existence on the right side of the speech center in left-handed people, may take up the function of the opposite side.

The tracing of any direct relationship between mind and body is a subject of large human interest. The work of Phelps is a splendid contribution to our knowledge, and outside of its medical value which is, of course, comparatively limited, marks an important step for the progress of physiology and psychology. It must be at once acknowledged, however, that the facts give no clue to the nature of mental processes. There is not the slightest bridging of the chasm between neural activity and mental states. There is still no answer to the question of where thinking is done, since there is no evidence whether this left prefrontal lobe is the center for direct control of mental phenomena, for mental co-ordination, or for mental inhibition. The point is one of brain topography rather than of pure psychology, and to quote Phelps, "if the same nature and degree of proof which is deemed sufficient for the localization of other cerebral functions may be accepted in the case of the mental faculties, their center of control has been established."

#### THE RENEWAL OF PRESCRIPTIONS.

The physician probably meets with no more unexpected surprises in ordinary practice than those which come from the renewal of his prescriptions. Some combination of drugs that he meant should meet a temporary indication and against whose prolonged use—if such a possibility had occurred to him—he would himself have been the first to protest, he finds at times has been used for long periods, perhaps even months. Fortunately, the human system, as a rule, soon accommodates itself to most ordinary drugs and accomplishes its work in spite of the disturbing element.

Occasionally a prescribed remedy becomes a sort of fetish with the patient, who is sure that he, or more often she, would not be well without it. Perhaps too, friends are persuaded to use the remedy for indications

utterly foreign to the conditions for which the original prescriber wrote.

If the renewal of prescriptions were always as harmless in its effects as we have thus suggested, it might seem idle to protest against it, but it is needless to say that there are many prescriptions that may do much harm if their use is prolonged. Pills containing nitrate of silver, for instance, may be indicated for the relief of long-standing gastric distress. They have been a favorite remedy of many of the older practitioners and their use is not infrequent at the present moment. This is just the sort of prescription that a patient may have renewed almost *ad infinitum*, for, after the severer symptoms of dyspepsia disappear, there will nearly always remain sufficient real or imaginary gastric disturbance to require remedial treatment—at least in the patient's mind. Besides, there is an ineradicable tendency in non-medical people to believe that what has done them good once will surely do good again, and the thought is sure to be entertained that a remedy which benefits may also act as a prophylactic. Several cases of argyria from the prolonged use of silver nitrate in no larger dose than one-fourth grain t.i.d. have been reported. Arsenic is another remedy whose cumulative effects may in susceptible individuals make themselves manifest after prolonged use of even small doses. The temptation to have prescriptions containing the drug renewed indefinitely comes very easily because arsenic has to be used for long periods to produce the desired effect.

If the personal inconvenience, or sometimes even serious disturbance, of the original patient were the only thing to be considered in this question of the renewal of prescriptions without a physician's advice, the state of affairs could not be nearly so bad as it actually is. Practically every one, not a physician, feels justified in recommending remedies to friends who seem to them to be suffering from an ailment like their own. Diagnosis is the most difficult thing in modern medicine, but for the lay mind there is no hesitation in deciding the character and significance of a friend's symptoms. A physician's reputation may suffer from diagnostic mistakes on the part of over-enthusiastic patients who insist on persuading acquaintances that the prescription that has helped them will surely relieve that friend's symptoms also. Some years ago a correspondent of the London *Lancet* called attention to an abuse of privilege in this matter that had proved actually detrimental to his own reputation. A patient suffering from specific sore throat with hoarseness as a prominent symptom was treated successfully by the usual specific remedies. A friend suffering from tuberculous laryngitis became persuaded that the same remedies might be useful in his case and took them for several weeks to the serious detriment, as might be expected, of his general health and, of course, without any relief of his throat symptoms. A third person, suffering from recurrent tonsillitis due to a chronic inflammatory condition, also took the remedies

for some time, naturally without any effect except an unwarranted prejudice against the doctor whose remedy did not help him. Such an annoying state of affairs may also develop when an anemic patient, by taking iron, is relieved of painful arthritic conditions due to lowered nutrition of the joint structures and persuades a plethoric individual suffering from subacute rheumatism, or an occupation neurosis, to try the same—but in this case contra-indicated—remedy.

The existence of an abuse in this matter of prescription renewal is well recognized. Many physicians have their prescription blanks printed with the express prohibition of renewal. This seems an eminently advisable precaution, under the circumstances, and, as far as possible, physicians should insist on the observance of the injunction. It is not often that prescriptions may be renewed without some change in their contents if the highest good of the patient is to be consulted. While the physician seems to be consulting his own interest by forbidding renewal and thus requiring further calls from the patient he is really assuring the best interests of the patient and of the community at large. There is entirely too much assumption of medical sapience by non-medical people. The practical expression of this takes the form of lending or passing on prescriptions. Physicians must at least secure themselves as far as possible against abuse of their prescriptions under conditions they would not approve. The mere insertion of the printed injunction not to refill will not effectually prevent the present abuse which is too deeply rooted in human nature to be thus easily gotten rid of. But it will help in the education of the public as to the dangers that exist in the practice and will act in most cases as an effectual deterrent at least of the frequent and prolonged repetition of a remedy without further consultation of the physician.

#### TOO MANY MEDICAL STUDENTS.

It has repeatedly been remarked in *THE JOURNAL* that the study of medicine is overdone, especially in this country. There come to our desk frequent reminders in foreign medical literature that we do not suffer alone, and that we have occasion also to feel for others' woes. A late item in the *Allgemeine Medicinische Centralzeitung* is to the point; the local medical association (Aerztekammer) of Austrian Silesia has published a warning to prospective medical students against entering upon their studies. It was specially resolved that a circular should be sent to the heads of the Silesian gymnasia calling attention to an already published appeal of the Vienna Students' Association in which the unfavorable outlook for the medical profession was shown. It was further resolved to publish similar notices in the political journals and to seek for coöperation of other medical bodies for the same general end. It evidently takes less to induce action over there than in this country for where they have one physician we have many. Moreover, they are not there multiplying medical colleges and otherwise working to cut their own throats finan-

cially by increasing their competitors in an already overcrowded profession. This is the case here; with a necessary reservation, that it is the few who profit by exploiting the mass of the profession.

#### IMPROVEMENT OF MILK SUPPLY.

The Department of Agriculture has just issued a neat pamphlet entitled "Market Milk: a Plan for Its Improvement" by Raymond A. Pearson, assistant chief of the Dairy Division of the Department. Its object is given in a prefatory statement, viz., to answer questions as to the means of improving the milk supply of communities by showing the ideal conditions or rather those that can be practically realized wherever it is seriously attempted. It does more than this, however, it lays down a plan of organization of local commissions mainly or entirely of physicians who are to educate the dairy men and the public as to the requirements of the ideal or model dairy product and to endorse the milk supply from such as furnish it under the proper conditions. The work of the local medical societies in New York and Philadelphia is noticed and the forms used by the Philadelphia Pediatric Society and the circular sent out by the New York County Medical Society are given in an appendix. While the methods proposed would require a revolution in the milk trade, they will ultimately have to be followed and the general circulation of this pamphlet will prepare the way not only by instructing the dairy men but by educating the public. There has probably been no more important minor publication issued by the Department than this one, and it is to be hoped that we shall before long see widespread results.

#### FIBRIN FERMENT IN MILK.

Studies with the various serums and anti-serums have led to the demonstration that milk, human and otherwise, generally contains fibrin ferment. This fact is readily demonstrated by adding a drop or so of milk to hydrocele fluid, which contains fibrinogen but no fibrin ferment, and coagulation results. We owe this observation to Moro and Hamburger<sup>1</sup> and Bernheim-Kauer.<sup>2</sup> Hydrocele fluid may lose the property of coagulating after standing for some days and after heating for thirty minutes to 55-56 C. The ferments in various milks do not react alike to heating, that in cow's milk not being affected by so low temperatures as the ferment in woman's milk. Bernheim-Kauer sought to obtain an antibody for the fibrin ferment in human milk by repeated injections of rabbits with milk, and with success. By suitable experiments with this anti-serum he shows that the ferment in cow's milk is not identical with that in human milk because the anti-coagulative action of the serum of rabbits injected with human milk is limited to human milk and does not affect to similar degree the ferment in cow's milk. He finds, further, that normal serum contains anti-coagulative substances in small quantities. To what extent if any the anti-coagulating substances normally present in the blood prevent clotting during life is as yet wholly conjectural. The observations referred to are interesting as far as they go.

1. Wien. Kl. Wochenschr., 1902, p. 121.

2. Centralbl. f. Bakt., 1902, xxx, 388-400.

No doubt further experiments will give us additional information concerning the origin and nature of this interesting ferment in milk.

#### ACID-PROOF BACILLI IN NON-TUBERCULOUS SPUTUM.

Several observers have found in the sputum from cases with pulmonary lesions, bacilli which are acid-proof and which closely resemble the tubercle bacillus on superficial examination. A. P. Ohlmacher<sup>1</sup> has reported finding an acid-resisting bacillus, which was at first mistaken for the tubercle bacillus, in the sputum from a case exhibiting certain clinical evidences of phthisis. He is of the opinion that the organism was identical with those described by Fraenkel, Pappenheim and Rabinowitsch in association with pulmonary gangrene. Lichtenstein<sup>2</sup> has also recently presented before the Berlin Society of Internal Medicine, a case in the sputum of which acid-proof bacilli were found. They were first mistaken for tubercle bacilli. The patient had had hemoptysis. Herr<sup>3</sup> has shown that acid-proof bacilli are widely distributed, not only upon grass and in cows' dung, but also in the dust from hay and in the soil of fields. In view of the fact that these acid-proof bacilli are so common in the external world, it would not be surprising if they should sometimes gain entrance to sputum or even be inhaled. That they may sometimes find favorable conditions for multiplication in the exudate in diseased lungs, in bronchial secretions, and in sputum is not unlikely. Some of these bacilli stain exactly like the tubercle bacillus, and to mistake them for the latter is excusable. In examining sputum for tubercle bacilli these facts are to be remembered, and thus something more complicated is introduced into what has usually been considered one of the most simple and accurate means of diagnosis.

#### A CANADIAN ANAXIAS.

In a leading article of a Canadian contemporary<sup>4</sup> on "The Canadian Summer" by one Ezra H. Stafford, M.D., we find the following remarkable statements adduced as evidence of the evil climate of the United States:

In the cities of the plains the temperature in July rises for many days in succession to 105 and over. During a summer's residence in Nebraska I painfully remember this period of protracted heat, which was so great that the brick-paved streets exploded with loud detonations, casting the bricks in all directions. There was no breeze, and fortunately, for any movement of the air only served to put in motion the suffocating alkaline dust that whitened on the banks of Salt Creek or was strewn in hot powder on the shores of Salt Lake. . . . In the large cities I have found the conditions quite as distressing. New Orleans is more endurable during the summer than Chicago, and San Francisco is more pleasant than either; but in Boston the humidity of the air renders the heat almost insupportable; while the contiguous resorts on the coast confer in the long run no more permanent ease than does the momentary application of cold to a fresh burn. In New York the heat seems to bring with it an even greater depth of despair. This is partially due to the fact that, in the matter of space, this city is architecturally constructed upon the frugal plan of a chiffoniere. It is nothing more or less than a huge piece of furniture in brick and iron; and serves to indicate the mon-

strous lengths to which the obsession of American utilitarianism can go. Baltimore and Washington I also found undesirable, and here malarial poison is added to the heat. . . . In July the Washington shopkeepers, to attract trade, fry eggs by breaking the shell and allowing the contents to fall upon the heated asphalt of Pennsylvania Avenue."

This is not offered as a joke, but seriously, as evidence of the conditions existing in the United States, and is published in a medical journal, presumably for the edification rather than the amusement of its readers. If the climate of Canada needs the support of such statements to demonstrate its comparative excellence, it is worse than it ought to be. In fact, they give it, to use a common expression, a black eye. The most serious consideration, however, is where do the author and the editor that publish such Munchausenisms as facts expect to go.

#### RENAL HEMATURIA OF TELANGIECTATIC ORIGIN.

That reddish discoloration of the urine is due to hemoglobin can be determined by spectroscopic examination and, if it be a result of hemorrhage, red blood-corpuscles will be discoverable microscopically. Hemoglobinuria is currently attributed to toxic influences of varied kind, but the exact mechanism of its production is not known. Hematuria may be secondary to a large number of conditions, some obvious, others obscure, and occasionally it may occur in the absence of any appreciable lesion. An unusual cause for such hemorrhage is described by F. Suter<sup>1</sup> under the caption of "Unilateral Hematuria due to Telangiectasis of the Pelvis of the Kidney." He reports the case of a woman, 32 years old, with hereditary predisposition to tuberculosis, whose urine, passed without difficulty, had been turbid and more or less bloody for a year and a half. No attention was given to this abnormality until the general health began to fail and the patient became pale and tired readily. On examination tenderness was discovered in the situation of the left kidney, without increased resistance or tumefaction. The urine contained blood, squamous epithelial cells and isolated leukocytes, but no renal elements and no tubercle bacilli. Cystoscopic examination showed the bladder to be normal, but the vesical orifice of the left ureter was small and through it bloody urine entered. Tumor or tuberculosis of the left kidney was suspected and lumbar nephrectomy was successfully performed. The removed organ was found entirely normal, but in the pelvis and the adjacent ureter a condition of disseminated miliary telangiectasis was found. The condition appears to be a rare one—at least not many cases have been reported and it is not generally referred to in the text-books. E. Hurry Fenwick<sup>2</sup> relates that he has repeatedly observed painless unilateral hematuria in young persons without the discovery, on nephrotomy and digital exploration of the pelvis of the kidney, of a cause for the hemorrhage. He reports two cases in which, when the pelvis of the kidney was opened and examination made with a cystoscope, a condition of telangiectasis of a papilla was found. Removal of the affected tissue was followed by cessation of the hematuria.

## Medical News.

### ARKANSAS.

**The gold medal** offered by the State Medical Society of Arkansas to the graduate of the State University passing the best examination in all branches was awarded to Dr. M. D. McClain; Drs. J. A. Bogart and E. Kreugar received honorable mention.

**Personal.**—Dr. George W. Hayman, Little Rock, has been appointed one of the colored commissioners of the World's Fair at St. Louis.—Dr. David A. A. Sims, Greenwood, has moved to Bonanza.—Dr. W. W. Jackson has been elected president of the Jonesboro Board of Health.

**Commencement.**—The twenty-third annual commencement exercises of the Medical Department of the State University were held at Little Rock, April 8. The annual address was delivered by Rev. Percy J. Robottom; the degrees were conferred on a class of 11 by the governor of the state, and the farewell of the faculty was pronounced by Dr. Edwin Bentley.

**Again in the Hands of the Law.**—Dr. Morris Hale, Hot Springs, was convicted, on April 16, of sending obscene and objectionable matter regarding the Alma (Mich.) Sanatorium, of which he was once superintendent, through the United States mails, and was sentenced to fifteen months' imprisonment at hard labor in the state penitentiary at Atlanta, Ga. This is his second offense.

### GEORGIA.

**Proposed New Laws.**—The bills proposed by the Medical Association of Georgia for passage at the next session of the legislature, provide that no prescription shall be refilled, and that patent medicines must have all of the constituent elements, and respective proportion of each element, distinctly set forth on the label.

**Personal.**—Dr. W. A. Brewster has resigned as superintendent of the City Hospital, Augusta, and will locate in Valdosta, June 1. Dr. Frank E. Williams, Tipton, has entered on his duties as interne at Lamar Hospital, Augusta.—Dr. M. W. Hollinshead, has decided to locate in Newman.—Dr. W. Hal Monerief, Atlanta, has passed his examination for the medical department of the Army.—Dr. Benjamin W. Bizzell, Atlanta, has been commissioned captain and surgeon of the Fifth Infantry, G. S. T., vice Dr. Edward C. Davis, Atlanta, resigned, and Dr. Bernard Wolff, Atlanta, assistant surgeon of the same command, vice Dr. J. Dawkins, Cromer, Atlanta, resigned.—Dr. James W. Eberhardt, Hartwell, has moved to Gilmer, Texas.

### ILLINOIS.

**Grand Army Mortality.**—The report of the medical director of the Illinois department, G. A. R., shows that the deaths during 1901 in that department numbered 683, a mortality rate for the year of 3 per cent.

**Insane Hospital Maintenance.**—The cost of maintaining the Bartonville insane hospital is higher with one exception than that of any other state institution of its character. The average cost of keeping each inmate during the first quarter was \$61.74. The best record during the quarter was made at the Jacksonville hospital, where the average per capita cost was \$31.13. The high per capita cost at Peoria is said to be incidental to the opening of the institution.

**Personal.**—Dr. John W. Parmely, Anna, has returned to his former home at Golconda.—Dr. Joseph Perkins, Rardin, has moved to Fair Grange.—Dr. Samuel Glasford, Pekin, has located in St. Louis.—Dr. R. W. Markley, Blackstone, is about to move to Elgin.—Dr. Charles R. Bird, Toledo, has located in Indianapolis.—Dr. James S. Collins, Carlinville, sailed for Europe on the "Pretoria," April 29.—Dr. Emmet Enos, late chief of staff of the Illinois Eastern Hospital for the Insane, Kankakee, has located in Herscher.—Dr. Benjamin G. Pinkerton has returned from an eight-months' stay in Syria and Egypt, and will practice in Springfield.—Dr. Charles H. Walters, Springfield, has moved to Taos, N. M., where he will have charge of the Franklin Placer.—Dr. Isaac B. Eunis, Gilman, has located in Rock Island.

### Chicago.

**Personal.**—Dr. J. M. Mitchell has located in Pontiac.—Dr. Dwight C. Orcutt sailed for England, May 3.—Dr. Martin Strand has moved to Chicago Heights.—Dr. Charles E. Parker has opened an office in Sterling.—Dr. Edwin A. Weimar has returned to Pekin to locate.—Dr. D. A. K. Steele

and wife have returned from a three-months' trip to Egypt and Palestine.

**Chicago Surgeon Wounded.**—Major Ralph S. Porter, U. S. V., who was seriously wounded in the battle of Bayan, Mindanao, entered the volunteer service as first lieutenant and surgeon of the Second Illinois Infantry in 1898. He afterwards was appointed first lieutenant and assistant surgeon of the Thirty-first U. S. Volunteer Infantry, and later rose to his present rank.

**Successor to Dr. Fenger.**—Dr. Arthur Dean Bevan has been appointed professor of surgery in Rush Medical College to fill the position made vacant by the death of Dr. Fenger. Dr. Bevan graduated at Rush in 1883. He was an officer in the U. S. Marine-Hospital Service from 1883 to 1888, professor of anatomy at Rush from 1888 to 1900, and professor of surgical anatomy and associate professor of surgery from 1900 to 1902.

**Cook County Internships.**—For the examination for internes at Cook County Hospital, held May 1, 13 candidates appeared from the University of Illinois; 30 from the University of Chicago, and 16 from Northwestern University Medical School. Of these 16 received appointments—8 from Northwestern, 4 from Rush and 4 from Illinois. The highest mark made by a successful candidate was 421.6; the lowest, 366.2. Northwestern men won the highest three marks.

**The Week's Mortality.**—For the week ended May 10, the recorded deaths are 549, 45 more than for the preceding week and 78 more than for the corresponding week of 1901. Within the past fortnight there has been a marked change in the type of all the contagious diseases. Scarlet fever, diphtheria, whooping cough and measles are much milder than a year ago; so much so that measles, which is epidemic throughout all sections, caused only one death last week, whooping cough but three, diphtheria five and scarlet fever nine or ten less than the week before.

**Disinfection.**—Through the increase of the force of disinfectors three weeks ago every call for disinfection had been complied with at the close of the week—the first time in many months. This, together with the efforts of the Memorial Institute for Infectious Diseases in making increased provision for scarlet-fever cases, gives promise that the spread of the contagious diseases may soon be materially checked. Milder weather, by favoring ventilation and sunning of interiors, will also do much toward putting an end to their almost unprecedented prevalence. Advantage should be taken of every sunny day, not only in household, where there has been contagious illness, but by every housekeeper.

### KANSAS.

**Iola Hospital Open.**—The physicians in charge of the Iola Hospital announce that the institution is now ready to receive patients.

**Does Good by Stealth.**—A member of the faculty of Kansas Medical College, Topeka, who does not disclose his identity, has furnished the money to put up a \$10,000 addition to the college.

**Personal.**—Dr. George Howard Hoxie has opened an office in Lawrence.—Dr. Samuel W. Williston, Lawrence, has been appointed correspondent for the London Geographical Society.

—Dr. Barnard D. Eastman, Topeka, has been elected permanent superintendent of Christ Hospital.—Dr. W. McIlwain, Wabunsee, has located at Lone Wolf, Okla.

**No Chinese Provision in Law.**—"Dr." Ah Sam of Leavenworth and "Dr." Andrew Wu, of Topeka, Chinese doctors, have appealed to the board and to the governor not to molest them. Chinese practice medicine differently from Americans, and the legislature has made no Chinese provision in its law. The board is said to have taken the matter under advisement.

**He Wants a Diploma.**—A mandamus suit was filed in the Supreme Court, May 7, against the Kansas Medical College by J. P. Shelton, a student, asking the court to compel the college to issue him a diploma and give the degree of M.D. Shelton alleges that he had an understanding with the college whereby he should attend for a three months' term and receive a diploma. He says he has done this and has passed a satisfactory examination in all branches in the college, but is refused the diploma.

**The Law Upheld.**—As the Supreme Court has upheld the constitutionality of the medical registration law passed by the last legislature, the State Board of Medical Registration and Examination has instructed the secretary to commence prosecutions against all physicians practicing in the state who have

failed or refused to take out a license to practice. This action by the board will effect from 75 to 80 physicians in the state. The law says:

Any person who shall practice medicine or osteopathy in the state of Kansas without having received and had recorded a certificate under the provisions of this act shall be deemed guilty of misdemeanor and upon conviction thereof shall pay a fine of not less than \$50 nor more than \$200 for each offense, and in no case wherein this act shall have been violated shall any person so violating receive compensation for services rendered. It is the duty of the secretary of the State Board of Medical Registration and Examination to see that this act is enforced.

#### LOUISIANA.

**Eye and Ear Hospital.**—The annual meeting of the Eye, Ear, Nose and Throat Hospital, New Orleans, was held, April 16. During the year 5098 patients were treated, 1149 of whom came from outside parishes. The officers were re-elected.

**Cisterns to be Screened.**—At a recent meeting of the Orleans Parish Medical Society resolutions were adopted endorsing the ordinance now pending before the City Council and providing for the screening of all cisterns in order to prevent the breeding of mosquitoes therein.

**Alumni Meet.**—The annual session of the Alumni Association of the Charity Hospital of Louisiana was held April 29 and 30. Dr. Lucien F. Salemon lectured before the Association on "The Rational Treatment of Typhoid Fever," and on the following day Dr. Frederick W. Parham spoke on "The Present Status of the Roentgen Rays as a Therapeutic Measure." The annual banquet was given at Lamothe's, April 30, after the business session.

**Tulane Commencement.**—The commencement exercises of the medical department of Tulane University, New Orleans, were held April 30. The annual address was delivered by Robert B. Fulton, LL.D., chancellor of the University of Mississippi. President E. A. Alderman of the University conferred degrees on a class of fifty. The small number of graduates is said to be due to the fact that this is the transition period from the three-year-course regime to that of the four-year course.

#### MARYLAND.

**Medical Society Banquet.**—The fifth annual banquet of the Baltimore County Medical Association was held at the Overland Hunt Club, Towson, May 14.

**Personal.**—Dr. Charles F. Davidson, Easton, has been re-elected a member of the State Examining Board.—Dr. T. Ross Payne has been appointed secretary of the Sanitary Board of Baltimore County. The sanitary physicians met for organization, May 14.

**Annapolis Emergency Hospital.**—A meeting of physicians was held, April 30, at the building recently purchased to be used as the Emergency Hospital of Annapolis. Drs. Frank R. Smith, Thomas S. Cullen and Joseph C. Bloodgood were elected members of the consulting staff, and the physicians of Annapolis named as the attending staff.

#### Baltimore.

At the Johns Hopkins Historical Club, May 12, Dr. Bernard Sachs of New York read a paper on "Hindoo Medicine," and Dr. William Osler exhibited a collection of Jenner's original publications, which had been bequeathed to him by the late Dr. Hunter McGuire, of Richmond, Va.

**To Complete Endowment.**—A committee of 70 citizens has been entrusted with the duty of raising the remainder of the endowment required by the Johns Hopkins University; \$800,000 are in hand, and it is hoped to complete the million by commencement day, June 10. A system of municipal scholarships is proposed and meets with the approval of the mayor.

**The Maryland Medical College commencement** was held May 13, Capt. Richmond Pearson Hobson, U. S. N., being the orator. The introductory address was made by Dr. Bernard P. Muse, the degrees conferred by Dr. John B. Schwatka, and the prizes awarded by Dr. J. Charles Linthicum. There were 39 graduates. E. F. Peters took the first prize, J. M. Graham second, and J. H. Caboon third.

**Health Wardens Must Marry.**—The *Minneapolis Tribune* announces that the health commissioner of Baltimore, who has a staff of twenty-four health wardens, has issued the fiat that the doctors in his employ must marry. His reason is that the department demands the service of steady men, and that a man is not apt to settle down to the serious business of life until he has a wife to take care of.

**Personal.**—Drs. Edward C. Moriarity and Charles H. Blake have been appointed resident physicians at the Baltimore University Hospital.—Dr. Frank O. Miller, a recent graduate of the University of Maryland, has been appointed a resident physician of the insane department of Bayview Asylum.—W. C. Gewin was appointed resident physician at the Franklin Square Hospital, with F. E. Smith, associate.

**The Baltimore Eye, Ear and Throat Charity Hospital reports** for the past year 5055 patients applying for treatment, 3162 white and 1873 colored. This is an increase of 8 per cent. over last year. The cases were divided as follows: Eye department, 3175; ear, 913; throat, 937. The dispensary visits numbered 17,745, about 60 per day. The indoor department has been reorganized, and there is now a corps of trained nurses who are always on duty. Nurses are obtained from one of the general hospitals, are given special instruction in the care of eye, ear and throat cases, and on the expiration of four months' service, if satisfactory, they receive a certificate. This is effected at but slight additional cost.

**Awarded the Boylston Prize.**—Dr. Robert Lee Randolph, associate professor of ophthalmology and otology in the Johns Hopkins Medical School, has been awarded the Boylston prize by Harvard University for his essay entitled "The Role of the Toxins in Inflammations of the Eye." The contribution is experimental in character, and the author has been at work on it for the past two years in the pathologic laboratory of the University. Among other things the work shows that not only do the bacteria themselves produce inflammation when brought in contact with the eye, but that their toxins can produce it also. Many bacteria, however, have not the power to produce these soluble toxins. Dr. Randolph shows that our ideas on this subject need revision, and that many bacteria probably produce inflammation through the agency of properties which previous tests have failed to discover. It is also shown that many of the most serious external inflammations of the eye are caused not only by the presence of bacteria between the lids and eyeball, but that the harmful effects of these bacteria are rendered more certain if the individual should rub the eye when the infectious material flies into it. The rubbing removes the epithelial covering of the eyeball, and thus an entrance is made through which the bacteria, which are always present, can enter the tissues. For instance, when certain organisms suspended in sterile water are dropped continuously upon the normal eye of a rabbit, even for a considerable time, no inflammation results, but let a slight wound or abrasion of the eyeball be made and inflammation always follows. The practical bearing of this discovery is obvious. Eyes into which infectious or irritating substances have entered, should never be rubbed, although the inclination to do this is usually very strong. The Boylston prize rarely finds its way out of New England. Dr. Randolph was awarded the Alvarenga prize by the University of Pennsylvania in 1900 for an experimental work on the crystalline lens. He was one of those who received the honorary degree of M.A. at the recent jubilee of the Johns Hopkins University.

#### MISSOURI.

**Jewish Hospital Opened.**—The new Jewish Hospital at Kansas City was formally opened May 4.

**Dr. Dickerson's Will.**—The will of the late Dr. D'Estaing Dickerson of Kansas City provides for a bequest to Albany Medical College, but leaves the bulk of the estate, which is valued at from \$700,000 to \$1,000,000, to his widow, who is appointed executrix without bond.

**More Honors for Dr. Gregory.**—At the commencement exercises of the medical department of Washington University, St. Louis, May 8, the faculty of the institution presented Dr. Elisha H. Gregory with a portrait of himself and a loving cup, the presentation being made by Dr. Norman B. Carson.

**Marion-Sims-Beaumont Graduation.**—The graduating exercises of this medical college were held in St. Louis, May 1. Degrees were conferred on a class of 91 by Dr. Young H. Bond, president of the college; Hon. George Tansey delivered the address and Dr. William G. Moore presented class honors.

#### MONTANA.

**Hospital Dedicated.**—St. John's Hospital, Helena, was dedicated with appropriate ceremonies by Bishop Brondel, April 1.

**Buys Sanatorium.**—Dr. James F. Blair, Butte, has purchased the Foster Sanatorium at Butte for \$25,000 and will take possession about May 25.

**Fire at Big Timber.**—A fire, on April 20, in the office of Dr. William A. Moore, Big Timber, destroyed papers and instruments valued at several hundred dollars.

**The "Spotted Fever" Epidemic.**—The epidemic of cerebro-spinal meningitis in Bitter Root Valley has caused 8 deaths during the last week and the state health officials are reported as being seriously alarmed over the condition. A conference was held at Hamilton, May 1, between Dr. William P. Mills, Minvula; Commissioner J. A. Ferguson of the State Bureau of Agriculture, and the officials and physicians of Ravalli County, relative to the adoption of measures to suppress the epidemic.

#### NEW HAMPSHIRE.

**Gift to Hospital.**—The children and grandchildren of the late Edward Joslin of Keene have presented \$12,000 to the Elliott City Hospital for the construction of a nurses' building, to be known as the Edward Joslin Home for Nurses.

**Imprisonment for "Greek Doctor."**—A. G. Zervoudaki, indicted for practicing medicine without a license in Summerworth, has been tried at Dover, found guilty and sentenced to be imprisoned for three months and to pay the costs of prosecution.

**School of Instruction for Health Officers.**—Under the auspices of the State Board of Health and the New Hampshire Association of Boards of Health a sanitary conference and school of instruction for health officers was held at the State House, Concord, April 29 and 30 and May 1.

**Sanatorium for Tuberculosis.**—The New Hampshire Surgical Club, at its semi-annual meeting in Manchester, March 26, adopted the following resolutions:

WHEREAS, The experience of the past years in the treatment of pulmonary tuberculosis at special institutions known as sanatoria, has resulted in the cure of the arrest of a very large majority of the cases received, and,

WHEREAS, Means should be provided whereby persons financially unable may receive the benefits of such treatment, therefore, be it

*Resolved*, That the New Hampshire Surgical Club recommends to the Legislature of 1903 a candid consideration of this subject, with the view to the establishment of a state sanatorium for the treatment of consumption.

#### NEW YORK.

**Bequest to Nyack Hospital.**—By the will of the late Dr. Charles H. Masten, of Nyack, about \$20,000 is bequeathed to the Nyack Hospital.

**Albany Hospital Internes.**—As the result of a competitive examination, held May 2, Drs. Willis G. Merriman, Jr., John Gutmann, Jr., and M. Joseph Mandelbaum have received appointments as internes at the Albany Hospital.

**Hospital Must Pay Duty.**—The United States general appraisers have handed down a decision which holds that the Albany Hospital must pay duty amounting to \$110 on the surgical instruments imported for use in the hospital by Dr. Maedenald in August, 1901.

**Albany Medical College** held its seventy-first annual commencement, May 6. Andrew Van Vranken Raymond, chancellor of Union University, conferred degrees on a class of 26. Dr. Samuel B. Ward announced the awards of prizes and appointments, and Hon. Nathan L. Miller, Comptroller of the State, delivered the annual address.

#### New York City.

**Addition to Long Island College Hospital.**—Henry W. Maxwell has purchased for the Long Island College Hospital property adjoining the hospital on which a dormitory, costing \$60,000, will be built for the use of the nurses of the hospital.

**Water Ambulance Launched.**—An electric launch specially constructed for the St. John's Guild floating hospitals for use between the floating hospitals and the Seaside Hospital at New Dorp, S. I., was launched, May 2. The launch has been built to the order of Mr. Isaac N. Seligman, who presented it to St. John's Guild.

**Hospital's Change of Name.**—The name of the Colored Home and Hospital has been changed to the "Lincoln Home and Hospital." It has been designated as an ambulance station by the city authorities. The ambulance service will be amply provided for in the emergency ward. White and colored people have always been treated alike in the hospital.

**Avoidance of Extra Medical Publicity.**—Drs. William S. Gottheil and Milton W. Franklin desire us to publish a disclaimer of their responsibility for a postal card sent to the medical profession by an electrical firm and an article in a New York daily regarding the transmission of light through the

human body, in which their names were mentioned without their consent.

**Land for Columbia.**—A number of the friends of Columbia University, who are desirous that the university shall acquire the two blocks of land south of One Hundred and Sixteenth street, Manhattan, known as the "South Field," have made a formal offer to the New York Hospital to purchase the property for \$1,900,000, with the intention of giving the university an option to buy it at cost.

**Appointments to Honorary Offices.**—Commissioner Lederle of the Board of Health has given out the following appointments to honorary offices: Daniel Draper, Ph.D., consulting meteorologist; Dr. George Henry Fox, dermatologist; Stevenson Towle, sanitary engineer; Dr. Clarence C. Rice, laryngologist; Dr. Arthur B. Denel, attending otologist, and Dr. George F. Shradley, consulting surgeon.

#### Buffalo.

**Personal.**—George W. Crile, Cleveland, read a paper before the surgical section of the Buffalo Academy of Medicine on "Experimental Study of Surgical Shock."—Drs. Harry Rooth and Marshall Clinton were elected president and secretary respectively of the surgical section of the Buffalo Academy of Medicine.—Drs. A. W. Hengerer, L. Page and Charles Denman have been appointed resident physicians to the German Hospital.

#### OHIO.

**Sanatorium Sold.**—Maysville Sanatorium has been sold to Drs. Charles D. Mills, Maysville, and Robert S. Carroll, Calvert, Texas.

**Hospital Appropriations.**—The Senate has appropriated \$35,000 for a new college at the Cleveland State Hospital and \$50,000 for a similar purpose to the State Institution for Epileptics.

**A Cleveland Philanthropist.** Mr. J. H. Wade, has given \$100,000 to the Cleveland Fresh Air Camp, \$100,000 to Lakeside Hospital, and \$50,000 to the Cleveland Day Nursery and Kindergarten Association.

**Verdict Against Doctors Set Aside.**—Judge Williams has set aside the verdict for \$1000 for malpractice recently obtained by Mrs. Beebe Guthrell against Drs. Will J. Means and J. Willcheur Barnes, Columbus, and has granted the defendants a new trial. He took the ground that the verdict was not supported by the weight of the testimony.

**Banquet to Dr. Weber.**—A reception and banquet was given to Dr. Gustav C. E. Weber of Cleveland, under the auspices of the Cleveland Medical Library Association, May 8. Dr. Harris G. Sherman was toastmaster. While the banquet was in progress Dr. Weber was stricken with apoplexy. He has now regained consciousness and there are hopes of his recovery.

**Personal.**—Dr. Harry H. Drysdale, assistant physician, Massillon State Hospital, has resigned to accept the position of physician-in-charge of the sanatorium at Lodi.—Dr. Eugene G. Carpenter has been reappointed superintendent of the Columbus State Hospital.—Dr. Charles W. Newton, Toledo, has been appointed Workhouse physician.—Dr. Sterling B. Taylor, Columbus, has been appointed medical examiner for the civil service commission, vice Dr. Harry M. Taylor, resigned.

**The New Health Code.**—Under the provisions of the new code recently enacted, boards of health are composed of five instead of six members, and the mayor is not a member of the board. Three members constitute a quorum. The present members of the board serve out the terms for which they were appointed. In hamlets and villages of less than 2000 inhabitants the council may appoint a health officer in lieu of a board of health, but such appointee must be approved by the State Board of Health. If any city, village, hamlet or township fails or refuses to establish a board of health or appoint a health officer, then the State Board of Health may appoint a health officer for such city, village, hamlet or township, and fix his salary and term of office. The salary of such health officer, and the expenses created by him in the discharge of his duties, become a charge against said city, village, hamlet or township. Entirely new provisions are made for the prevention of contagious and infectious diseases. The duration of quarantine in smallpox, diphtheria and membranous croup and scarlet fever is fixed. It is left optional with boards of health to quarantine measles, chickenpox or whooping cough. The Board of Health is required to disinfect any house or room in which a person has been ill with any of certain named contagious diseases; and it is a misdemeanor to rent any such house or rely

until disinfection has been carried out. Disinfection is to be done at public expense, and boards of health are authorized to purchase disinfecting apparatus and supplies.

#### Cincinnati.

**Faculty Changes.**—Additions have been made to the faculty of the Miami Medical College as follows: Dr. William E. Lewis, professor of anatomy; Dr. William H. Wenning, professor of clinical gynecology; Dr. John M. Withrow, professor of clinical gynecology; Dr. George A. Fackler, professor of clinical medicine, and Dr. Mark A. Brown, professor of hygiene.

**Improvement of Cincinnati Hospital.**—The authority to issue bonds to the extent of \$500,000 for the improvement of the Cincinnati Hospital having passed both houses of the legislature, Drs. Holmes and Isham and Mayor Fleischmann of the hospital board have been appointed a committee to devise plans of procedure for spending the money. Hon. Prescott Smith was appointed a committee of one to test the constitutionality of the act under which the allowance was granted, so that there may be nothing in the future to retard the progress of the new building contemplated.

**The commencement exercises** of the Medical College of Ohio were held May 6. The valedictory was delivered by Dr. Benjamin K. Rachford. A class of forty-two received their degrees from President Ayers of the University; Dr. Phineas S. Conner delivered the faculty address, and Dr. James G. Hyndman announced the awards of prizes.—On May 1, the Miami Medical College graduated a class of thirty-three, the largest for several years. The valedictory was delivered by Dr. Charles E. Goss, who made a strong plea for the endowment of medical colleges.

#### PENNSYLVANIA.

##### Philadelphia.

**Dr. George Gottstein**, first assistant to Professor von Mikulicz, University of Breslau, Germany, was recently a visitor at medical schools and hospitals of the city.

**Library Report.**—The librarian of the College of Physicians reports, for the month of April, 227 volumes, 491 pamphlets, and 2708 journals received. The donors numbered 60.

**Appointments in Jefferson.**—Dr. Max H. Bochrach has been appointed demonstrator of nervous diseases; Dr. Alfred Gordon, instructor in nervous disease, and Dr. William C. Pickett, instructor in insanity.

**The Nathan Lewis Hatfield Prize for Original Research in Medicine.**—For the best essay in competition for this prize, the College of Physicians announces, through its committee, that \$500 will be awarded. The subject specified is: "The Relation Between Chronic Suppurative Processes and Forms of Anemia." Essays must be submitted on or before March 1, 1903. The treatment of the subject must include original observations or researches or original deductions. The competition is open to members of the medical profession and men of science of the United States. Particulars may be obtained from J. C. Wilson, M.D., chairman, College of Physicians, 219 South Thirteenth Street, Philadelphia.

#### GENERAL.

**Health of the Troops in the Philippines.**—The latest report received, May 2, 1902, at the office of the Surgeon-General of the Army, is that dated March 15, 1902, from Lieut.-Colonel Charles Heizmann, chief surgeon of the Division of the Philippines. The strength of the command during the month ended on the latter date was 35,814 men, with a percentage of sick to the command present of 6.45. This rate is practically the same as that for the month immediately preceding and is regarded as satisfactory. Of the total sick present 20.99 per cent. were affected with venereal diseases; 10.12 with dysentery, 6.44 with diarrhea and the same percentage with malarial fever. Injuries constituted 10.12 per cent. of the total. From a careless examination of this record, venereal diseases are liable to be regarded as extremely prevalent, as 20.99 per cent. of the cases under treatment. It should be remembered that the total of the cases constituted 5 per cent. of the command, so that the venereal diseases formed only 20.99 per cent. of 6.45 per cent. of venereal disease in every 1000 men present. The surgeon remarks that while it is believed that the venereal diseases of enlisted men will hold this moderate figure, there is now little concern as to the prevalence of the disease in the provinces, and that a slight increase may be expected from month to month.

The number of deaths in the division decreased from 54 to 43, dysentery being responsible for 11 and variola for 3 of the fatal cases.

Bubonic plague had not attacked the command during the month and had been discovered in but two civilians, both natives, in the San Nicholas District of Manila. The board of health is continuing its active measures for the suppression of the disease. It is believed in Hong Kong that there will be little plague this year, either there or in Manila, and as the experience of that board with the disease extends as far back as 1894, its opinion is of value. An active epidemic of cholera was in progress at Canton, with rumored cases in Hong Kong at the time the chief surgeon wrote. The commerce with the latter port makes this a matter of importance, although the efficient work which the Marine-Hospital Service is doing in guarding the Philippines from epidemic diseases renders the introduction of cholera improbable. The possibility must be recognized in the cases of stowaways and of those smuggled into the minor ports. Cholera appeared twice in the Philippines in epidemic form, both times in the '70s, killing in the more severe visitation over 30,000 people.

#### Smallpox.

**Delaware:** On account of the prevalence of smallpox at the Delaware State Hospital, Farnhurst, the trustees held their regular meeting at the Wilmington Club May 2. The smallpox situation was discussed, and it was stated there had been twenty-one cases and three deaths had been the result since the outbreak. The patients have now been removed to the Emergency Hospital, and it has been fenced in to prevent the escape of insane patients.

**Illinois:** At Monmouth, neighbors of a man affected with smallpox burned the house in which he was quarantined, the patient and his wife escaping with difficulty.—Fifty Chicago & Northwestern track layers are quarantined in boarding cars at Elva. A bad case of smallpox has developed among them.—The school children at Montrose will lose a month of schooling on account of smallpox.—It is reported that 25 known cases of smallpox exist in Staunton, Macoupin County.—Smallpox in Chicago has changed from the mild type to a much more severe form, as noted in the Bulletin of April 19, and the first deaths from the disease since January 3 occurred during the week. This disease, however, is of minor importance in Chicago, as it is in any well-vaccinated community. Of the total 169 cases discovered and treated since the first of the year not a single one had ever been properly vaccinated and the great majority of the victims come from the lowest classes.

**Indiana:** The Vanderburg county council, at a special meeting Thursday, made an appropriation of \$4000 for smallpox in the county. This makes a total of \$14,500 appropriated this year for smallpox purposes. In all, there have been 268 cases of smallpox in the county this year. There are now eighteen cases in the pest-house.—Mrs. Joshua Collins, Southport, is dead from smallpox and seven other members of the family are suffering from the same disease. She belonged to a sect known as the "Church of God," which claims there is no warrant in the Bible for vaccination.—Secretary Hurty, of the State Board of Health, who returned May 2 from Shelburn and Hymera, says there are more than a hundred cases of smallpox there. Health officers, he declares, are badly handicapped in fighting the disease by lack of funds.—At the Indiana Reformatory, Jeffersonville, fifteen cases were reported and the remaining twelve have broken out so far this month. Vaccination was not as thorough as it should have been, on account of the contractors demurring against all of their men being idle at the same time.—Fontanet has 7 new cases of smallpox.—Dr. James N. McCoy, of Vincennes, was arrested May 8 on the charge of breaking the quarantine law by taking three negroes afflicted with smallpox to the polls at the recent election. He pleaded not guilty and was placed under a \$100 bond to appear for trial in the Knox Circuit Court, May 25.

**Kansas:** Smallpox has broken out in the State Industrial School for Boys, Topeka. Eight cases have appeared already. Seven of them are boys who are inmates of the school and the eighth is an employee.—A lay report in the *Kansas State Journal* of May 8 alleges that Garden City is full of smallpox. Out of the possible 1500 inhabitants of that town 200 are either convalescing or breaking out with what the physicians advertise as "Cuban itch," which is really smallpox. They have it in a mild way, and the health authorities cheerfully overlook it.

**Maryland:** Five new cases of smallpox were reported in Baltimore during the week ended May 10. A white man, aged 65, was sent to quarantine May 9 with smallpox. This case

originated in the city and excites fear that the disease is gaining ground.—Three colored men who had been confined in the observation house of the health department developed symptoms of smallpox May 5 and were removed to quarantine. They contracted the disease at Sparrow's Point, a water suburb of Baltimore, where cases of the disease have recently occurred.

—The Commissioner of Health has permitted a limited number of students, under careful regulations, to see the cases of smallpox at the quarantine hospital. Sections of two classes have enjoyed this privilege, one under Dr. C. Hampson Jones, Assistant Health Commissioner, the other under Dr. John S. Fulton, Secretary of the State Board of Health.

Michigan: There were 5 deaths from smallpox during April in the following localities: Benton Township, Cheboygan County, Belding City, Ionia County, Fairplain Township, Montcalm County, Croton Township, Newaygo County and Buena Vista Township, Saginaw County.—Smallpox was reported present at 110 places, May 1.

Minnesota: Six cases of smallpox have appeared in one family in Minneapolis.—Dr. H. M. Bracken, secretary of the State Board of Health, and the surgeons of the railways running out of Minneapolis and St. Paul, held a conference May 2 to devise means by which the spread of smallpox among the trainmen might be restricted. The consensus of opinion as to the best method of regulating the matter seemed to favor compulsory vaccination of all employees.—The smallpox report for the week ending April 28 showed 263 new cases in the state, distributed among 40 counties and 70 localities. The previous week's report gave 140 new cases in 54 localities and 35 counties. Todd County takes the lead, with 42 new cases, 31 in Staples Village, and 11 in Gordon Township. Hennepin County reports 38, 16 in Crystal Lake Township and 10 in Minneapolis; Scott County 22, 18 in New Market Township; St. Louis County 16, 12 in Duluth; Blue Earth County 14, 11 in Mankato; Otter Tail County 12, and Meeker County 10. Ramsey County has six new cases, all in St. Paul. No deaths are reported.

Nebraska: During the week ended May 10, 17 new cases of smallpox were discovered in Lincoln.

New York: The death from smallpox of an attendant employed in Long Island State Hospital, King's Park, as well as the development of another case, making the fourth, has resulted in a general quarantine of the entire institution.—A Buffalo priest who had been asked to minister to a dying smallpox patient, and who thus exposed himself, has contracted the disease and was sent to the quarantine hospital.

Ohio: Smallpox is reported as follows: Point Pleasant, 18 or 20 cases; Cleveland, 13 cases; North Baltimore, 7 cases.

Pennsylvania: Assistant Medical Inspector Alexander C. Butcher, Philadelphia, had his attention called late yesterday afternoon to two suspicious cases of illness in Hutton street. He visited the premises and found that the patients were suffering from smallpox. The authorities had the patients removed at once to the Municipal Hospital and quarantined the entire block. A corps of physicians was then sent to vaccinate the inmates of all the houses.

South Carolina: In the report of the health officer of Charleston for 1901 the outbreak of smallpox receives special attention. Before March 6, 1901, there had been but one case in the city (imported in 1900) in several years. After March 6, when the disease again appeared, there were 54 cases—9 white and 45 colored—all traceable to sources outside the city. The disease was for the most part of a mild type, and no death occurred. Active methods, by quarantine, vaccination, etc., were employed to prevent its extension and it was speedily suppressed. In "no instance did it spread," even to occupants in other rooms in the house where it appeared. The work of vaccination, it is noted, "was most thoroughly and efficiently done." At least 30,000 persons, or more than half the population of the city, were vaccinated in a few weeks.

South Dakota: Crazed by whisky, three patients in the county pest-house at Deadwood ended a night of riot May 2 by setting fire to the building and destroying it, after they had overturned beds and destroyed the furniture. The other patients, many of whom were in the worst stages of smallpox, narrowly escaped death, being rescued with difficulty. A temporary shelter was found for them after they had spent nearly all the night on the hillside.

Tennessee: Obion is still suffering from smallpox. There are twenty or thirty cases there. There have been two deaths from the disease, and three of the victims are not expected to recover. The disease has been more virulent there than anywhere in that section of country.

Utah: At the close of last week there was one case of smallpox in the detention hospital at Salt Lake City. Four new

cases developed during the week and none having been discharged, left 5 cases at the close of this report.

Canada: In addition to two cases of smallpox in Nelson, British Columbia, a case is reported from Kitchener on the Crow's Nest and a suspected case from Slocan City, which came down from the Enterprise mine. At Slocan City twenty-five people are quarantined, but no case has developed. A man who escaped from quarantine at Nelson was captured at Ymir.

#### CANADA.

**No Compulsory Vaccination for Montreal.**—The Montreal City Council voted down the by-laws, making vaccination compulsory, by a very large majority. This vote has been registered in face of the fact that the Provincial legislature had passed an enactment giving the Quebec Board of Health power to order the City Council of Montreal to pass an act making vaccination compulsory. Although the great value of vaccination has been strikingly proven by recent events in Montreal the council thus puts itself on record. In the recent outbreak of smallpox in that city, out of 361 patients, only three bore good vaccination marks; 322 of the 361 had never been vaccinated at all. The outbreak of the disease has cost the city thousands upon thousands of dollars, and all because people would not be vaccinated. Over three hundred municipalities of the Province of Quebec have already passed this compulsory vaccination by-law. The metropolitan city of the Dominion has rejected it.

**The Golden Jubilee of Three Montreal Physicians.**—The medical profession of Montreal tendered a banquet, April 30, to three of the most distinguished medical men in that city, viz.: Dr. J. P. Rottot, dean of the Laval Medical Faculty; Dr. D. C. MacCallum, emeritus professor in the medical faculty of McGill; Sir William Hingston, professor of Clinical Surgery at Laval, and one of the founders of the medical faculty of Bishop's. Dr. F. W. Campbell, dean of the faculty of medicine at Bishop's, occupied the chair. The occasion was the fiftieth anniversary of the entering of each of these into the ranks of the profession of medicine. Dr. Rottot was admitted a graduate of the old Montreal College of Medicine in 1847, which afterward became the Victoria, and now is the medical faculty of Laval. Dr. MacCallum graduated at McGill in 1850, and subsequently held the chair of obstetrics in that institution for many years. Sir William Hingston graduated in 1851 from McGill. He has been mayor of Montreal, and is now a senator.

**Canada To Have a Dominion Medical Council.**—Dr. Roddick's Bill for a Dominion Medical Council has passed its third reading in the House of Commons, having been opposed by only sixteen members, all of whom are from Quebec constituencies. Dr. Roddick had the following amendment added to the bill: "No province shall be represented upon the council either by appointed or elected members until the legislature of the province has enacted in effect that registration by the council shall be accepted as equivalent to registration for the like purpose under the laws of the province, provided that when all the provinces of the Dominion shall have legislated in effect as aforesaid, it shall be lawful to appoint and elect in the manner aforesaid members of the council representing the provinces which have so legislated, universities and incorporated schools aforesaid, situated within such provinces, and such members shall subject to the provisions of this act, constitute the council." Both Sir Wilfrid Laurier, the leader of the government, and the Hon. R. L. Borden, the leader of the opposition, supported the measure.

#### FOREIGN.

**A new Chinese hospital** is being built at Canton, China, by the French. Ground was given and the Chinese contributed \$90,000.

**Kyoto Asylum Burns.**—The Funaokayama Lunatic Asylum at Kyoto, Japan, burned April 19, and 18 of the 39 inmates perished.

**Foreign Medical Students in France.**—The number of foreign medical students in France has constantly decreased since more stringent regulations were introduced about 1895. There are now 764, while in 1894 there were 1054. Russia and the southern countries of Europe afford the largest contingent, Turkey, Roumania, Greece and Bulgaria. There are 6 students inscribed from the United States; 16 from South America; 11 from the Antilles, and 8 from Central America, with 3 from Mexico. The total number of French medical scholars is 7118, or 7882 in all, of whom only 54.8 per cent. are inscribed at Paris.

**Transvaal Medical Practice.**—A proclamation, noted in the *Consular Reports*, provides that licenses must be obtained by

persons (not already duly admitted to practice) as physicians, surgeons, dentists, chemists or druggists. The license is to be obtained from the secretary of the Transvaal administration, and before obtaining it a diploma or certificate entitling the holder to practice in the country where it was granted must be submitted. The license will not be granted unless it is shown that in the country which conferred the diploma, British subjects legally qualified to practice medicine in Great Britain are afforded privileges equivalent to those granted by license under this proclamation.

**French Medical Congress.**—The Sixth French Congress of Internal Medicine met at Toulouse in April with Lemoine of Lille in the chair. Three notable addresses on "Hepatic Insufficiency" opened the proceedings. In the first Charrin described the results of his personal researches which have demonstrated among other facts the constant existence of degeneration of the liver in the fetuses of women diseased during their pregnancy. In one case there was actual cirrhosis of the liver in a prematurely born infant who only lived one or two days and no germs could be detected in the liver. He thinks that the insufficiency of the liver noted in eclampsia is merely an exaggeration of the processes which occur physiologically during pregnancy. Ducamp proclaimed that intermittence in the elimination of methylene blue is the most reliable and constant sign of hepatic insufficiency. He added that insufficiency of the kidneys may abolish all the signs of insufficiency of the liver. Hepatic organotherapy will be found useful in the form of hepatic insufficiency characterized by continuous glycosuria, exaggerated after meals, associated with hypozoturia, urobilinuria and indicanuria and occasionally with gingivitis, impotence, neuralgia, cutaneous lesions or a cataract. Ver Eecke described the therapeutic indications which can be deduced from study of the effects of experimental ablation of the liver. The other addresses were on "Convulsions in Children" and "Anti-Waste Medicines" (Médicaments d'Épargne). The *Semaine Médicale* of April 2 to 16 contains the full text of most of the numerous and valuable communications, including those on "Treatment of Parasymphilitic Affections," "Dysenteric Endocarditis," "Diagnosis of Abdominal Aortitis," "Fixation Abscesses," "Diagnosis of Variety of Aneurysm of the Aorta from the Aortic Pulse," etc.

**German Medical Congress.**—Naunyn presided over the Twentieth Congress of Internal Medicine, which met at Wiesbaden, April 15 to 18. Ewald and Fleiner delivered addresses on the "Diagnosis and Treatment of Gastric Ulcer" and Bie of Copenhagen on "Phototherapy." The latter denied that the isolated chemical rays are more powerful than the undecomposed white light; in fact, the reverse is true. The benefit derived from red light in smallpox is due to the exclusion of the injurious chemical rays, and it should be so perfect that a photographic plate exposed in the room does not become altered. He stated that Finzen's Institute has treated 640 cases of lupus and permanently cured 456. About 15 per cent. of all cases have proved rebellious, but even the most malignant cases were not excluded from the treatment. The curative results in eczema and other cutaneous affections have been very satisfactory, but not so brilliant as in lupus. The chief interest centered in Von Leyden's address on the "Parasitism of Cancer" on the eve of his birthday. He stated that only the permanent irritation of a living body can explain the constant growth and proliferation of the cells in cancer. It does not devour the cells, but stimulates them to proliferation like the similar excrescences on plants, especially "cabbage hernia." The clinical picture of carcinoma has many points in common with an infectious disease. He knows of a case in which a young physician drank by mistake the juice squeezed out of a carcinoma, and died two years later from carcinoma of the stomach. Naunyn also reported the case of a physician who exhibited evidences of carcinoma of the stomach three months after he had inadvertently drunk the fluid which had been siphoned out of the stomach of a cancer patient. Von Leyden has lately succeeded in finding sporulation-forms of the endocellular bodies—"Zelleinschlüsse"—which he accepts as the parasitic agent of carcinoma. He has also reproduced on other dogs carcinoma and even metastases after inoculation from a carcinoma of the penis on a dog. No experiments have yet been successful in which cancer was transmitted from one species to another, and even contagion of one person from another—although probable—has not yet been proved. The congress will convene next year at Leipzig.

**The International Conference of the Medical Press.**—France sent the most numerous contingent to this conference, which was held at Monaco, April 9, with 27 delegates in at-

tendance, all men of note and influence. The *British Medical Journal*, the *Lancet* and the *Clinical Journal* were the English journals represented. Germany sent the editors of the three great weeklies, Austria one, Belgium three, Spain two and Italy three, including the editor of the *Riforma Medica*, the only medical daily in the world. The duly approved delegates from Hungary, Sweden, South America, Canada, and the three from the United States were unable to be present, but their absence was excused. Russia refused to take part in the conference. The first article voted was that the association shall be composed of journals inscribed by their title and represented by a member of the staff, and secondly, of journalists, accepted by the National Press Association. In countries with no national organization the editors or secretaries of journals will be accepted as members if approved by the central committee of the International Association. Each journal may be represented at each general assembly by three representatives, but has only one vote. Each representative must agree to accept the regulations in respect to property in medical literature. The resolutions on this subject prepared by the committee (See THE JOURNAL, page 1017), were adopted with the addition that illustrations can be freely reproduced by other journals, on condition that the original source be cited. The question of exchanges between medical journals was the subject of much discussion, and the following proposition was finally voted: "Acceptance of exchange between members of the Association of the periodicals of which they are the directors or editors-in-chief. The exchange is based on the differential price of the subscription and postage, and with the reserve that the proprietor of the journal also accepts. If the request for exchange proceeds from a journal whose subscription price is higher than that of the one addressed, the latter has the option of declining." It was decided to publish an international bulletin; to provide international identification cards for members of the Association traveling in other countries, and to establish a code of telegraphic abbreviations and other measures to decrease the expense of communication between the medical press. Some of the delegates wished to abolish exchange altogether, but Laborde succeeded in maintaining it as a fundamental obligation and courtesy between members united and "solidarized" by the projected association. Detailed reports of the proceedings are being published in the *Gazette Med. de Paris*, whose editor is the general secretary of the International Committee of Organization.

## LONDON LETTER.

### The Smallpox Epidemic.

There are 1515 cases of smallpox in the metropolitan hospitals, against 1522, 1437 and 1431 in the 3 preceding weeks; 367 new cases were admitted during the week, against 376, 274 and 328 in the 3 preceding weeks. During the first quarter of the present year there were 734 fatal cases of smallpox in London, against 35 and 193 in the 2 preceding quarters. The deaths from smallpox last week were 42, against 54, 73 and 42 in the preceding 3 weeks.

### The Public Health.

The weekly returns of the Registrar-General for London and 75 other great towns of England and Wales correspond to an annual rate of 17 per 1000 of their aggregate population; in the preceding 3 weeks the rates were 17.6, 17.4 and 18.3. Of 55 fatal cases of smallpox, 42 belonged to London. The annual death rate of London was 17.4, against 17.9, 17.3 and 18.1 in the preceding 3 weeks.

### Vexatious Actions Against Physicians: The Case of Dr. Law.

Recently in THE JOURNAL the preposterous action of a nurse against Dr. Law for damages in consequence of becoming addicted to morphia, which he prescribed for her, was described. Of course, the action failed, but as usual in such cases, because of the poverty of the plaintiff, costs can not be recovered from her. Thus Dr. Law will have to defray very heavy expenses. The hardship is all the greater as his attendance—as is usual in the case of nurses—was gratuitous. However, the profession will show their practical sympathy. A meeting is to be held and many eminent physicians have promised their support.

### Conspicuous Delay of Growth and Development.

At the Clinical Society Mr. Hastings Gifford showed a remarkable case of arrest of development of a kind which has not hitherto been systematically described, though some dozen or more cases have been recorded by French and German writers. The patient was a man aged 28, of a healthy family. At 23 he was 1.078 meters in height (3 feet 6 inches) and had since

grown 18 millimeters. His height and proportions resembled those of a boy between the ages of 6 or 7. A radiogram of the hand showed that ossification was no further advanced than in a child of 10, and the dentition also corresponded to that age. The contour of the body and the appearance of the head and face were childish. The sexual organs were the most backward in development: the testes had not descended and the external genitals were infantile. The intelligence was good but the behavior and conversation were more like that of a child than an adult. The thyroid gland could be felt. The dwarfism was apparently not due to any known cause of that condition. Achondroplasia, rickets and microcephaly could be excluded.

#### The Plague in Egypt.

For the week ending April 13 there were 23 cases of plague in Egypt and 13 deaths, for the week ending April 20, 31 cases and 19 deaths. In the latter week 2 cases occurred at Alexandria, which has been free from the disease since February 17. In the Mauritius there were no cases for the week ending April 24.

#### Medicine and Egyptian Progress.

The annual report of Lord Cromer shows very gratifying progress of Egypt under British rule. The foundations of well-being and the material prosperity of a civilized community have been laid. From the medical standpoint progress is well marked. Well-equipped and well-managed hospitals are provided for the sick. The lunatic is no longer treated as a wild beast. The number of admissions to hospital continues to increase: 23,447 in-patients were treated in 1901, against 22,572 in 1900. Independently of plague, 3622 cases of infectious disease and 682 deaths were notified, against 4144 cases and 1027 deaths in 1900. Smallpox accounted for 1883 cases and 220 deaths. Cairo was comparatively free from the disease during the year, only 20 cases and 4 deaths occurring, against 172 cases and 41 deaths in 1900. This immunity was, no doubt, due to very thorough vaccination. The benefit of vaccination is illustrated by the epidemic in Port Said. The population consists of 35,000 natives and 12,500 Europeans. In 1901 smallpox broke out and there were 174 cases, 56 deaths. Of these, 129 cases and 38 deaths occurred in the Europeans, 45 cases and 18 deaths in the natives. This enormous disproportion was, no doubt, due to lack of vaccination among the Europeans, among whom, unlike the natives, enforcement of vaccination is not possible. Smallpox, which was formerly very prevalent in the province of Assouan, has been almost entirely stamped out by vaccination. In Cairo 357 cases of diphtheria occurred in 1901, against 210 in 1900. The difficulty of checking this disease arises from the fact that many cases are not brought under the notice of the sanitary authorities until after death. In all infected houses prophylactic injections of antitoxin are given to the surviving children when the parents accept it; in such houses second cases have never occurred. During the year 227 cemeteries were condemned and other sites were selected in lieu of them. The work of improving the sanitary condition of the mosques continues. There is a great difficulty of good water supply. The one source—the Nile—has from time immemorial been used as a main sewer. Arrangements have been made to supply several more provincial towns with good water. Borings have been successfully made and steps taken to prevent contamination. At Alexandria new filter beds are being constructed. In Cairo a system of surface drainage for the removal of storm water has been completed.

#### Plague in India.

The latest returns show that the disease is spreading. There were 26,108 deaths in the week ending March 22, against 25,655 in the preceding one. The Punjab shows the chief increase—16,829 deaths. In Bombay City the mortality continues to increase—1902 deaths were registered for the week ending April 2, of which 999 were due to plague.

#### Plague and Rats on Ships.

An outbreak of plague which has occurred in Western Australia is important because it shows in a striking manner how the disease is spread by rats on ships. The *S. S. Antillean* a troop ship of 3686 tons, left Capetown on Feb. 1, 1901, and entered Sydney harbor on March 2, having no cargo but shingle ballast. The health officer of the port was informed that all hands were well except a sailor who was thought to be suffering from pleurisy. It was known that plague had occurred at Capetown subsequently to the departure of the *Antillean* examination showed that he had plague. He was therefore removed to the hospital, where he died on March 3, and the vessel was sent to the maritime quarantine station; inoculation

was offered to all hands, but only 10 accepted. On March 12, a man who was a storekeeper on board, fell ill with plague. Two rats were found dead on the vessel on March 4—teeming with plague bacilli. The captain said that there were not many rats on board, but on February 22—the day of the departure of the vessel from Albany, Western Australia, where it had been for 24 hours—15 carcasses were discovered. At Albany the vessel anchored in the stream and received coal from a lighter which came alongside. Plague broke out immediately afterwards in Western Australia, but not in Albany: most of the cases occurred in Perth, 245 miles from Albany, but connected with it by rail. At Sydney the *Antillean* was fumigated 4 times with sulphur, more than three-quarters of a ton being burnt. The storerooms, having probably been the resort of rats, were twice sprayed with corrosive sublimate solution (1 in 500) by means of Geueste-Hirscher sprays, and were separately fumigated. After repeated searches only 83 dead rats were found. In reporting on this case Dr. Y. Ashburton Thompson, President of the New South Wales Board of Health, points out that plague communicated to 100 rats which infested a vessel continued among them for 29 days and yet at the end of the term it killed only a minority. Hence, a voyage within the limits common with steamships at the present day does not prevent infection of clean ports. Another fact of even greater practical importance is that a ship may be infected at a port under no suspicion of plague at the time. Generally communication of such a ship with clean port would be unrestricted and it appears that the epidemic at Sydney in 1900 originated in this way.

#### PARIS LETTER.

##### Legacies and Medical-Men in France.

There is a law in France that medical men can not receive any legacy from a patient whom they have treated during his last illness, and this law has been the cause of some complaint on the part of physicians. A member of the French parliament, Dr. Delarue, has advocated a change in this law, and his proposition has been sent before the committee of judicial reform belonging to the Chamber of Deputies. The corporation of physicians in France is well represented in the parliament, since it seems that there are about 50 doctors for 493 members of that body, and this new law will certainly find some zealous partisans.

##### Statistics of a French Sanatorium.

Dr. Sabourin, a well-known French physician, has recently published in the *Presse Medicale* the result of the treatment of consumption in the French sanatorium of Durtol. Out of a total of 250 cases, Dr. Sabourin has analyzed the number of patients cured. By this is meant that for three months there have been neither expectoration nor cough, that the patient looks well, and shows no reaction after exercise or any other causes which produce a change in a tuberculous patient. On their arrival at the sanatorium examination showed that, out of the total of 250 cases 100 had lesions which prevented all chance of a cure. Out of the 150 that were not too far gone 92 were discharged cured, which makes a percentage of 60 per cent. Of the 100 who were incurable 2 did ultimately recover. Out of the 94 cured 10 have since had a relapse. There were, therefore, 84 patients who recovered out of a grand total of 250, which makes a percentage of 34 per cent. The 94 patients were affected in the following manner: Fourteen had lesions of the first degree, 56 of the second, and 24 of the third degree.

##### The Fight Against Alcoholism.

The French Antialcoholic League has just distinguished itself by an act of courage, which is certainly to be admired in this epoch of trusts, combinations, and general exploiting of the public. This league has instituted legal proceedings against one of the most important manufacturers of absinthe, on account of the following advertisement, which has been appearing in several newspapers: "As oxygen has a special renovating and exhilarating power, Cusenier's oxygenated absinthe, green or white, is recommended rightly by doctors and sought after by amateurs." The medical profession was brought into cause, and such is the reason for this action. Cusenier is the great absinthe king in France, and it will be interesting to note the result against one of the evils of the age in France, the selling of poison to the population.

##### Calob's Treatment of Pott's Disease.

The treatment of Pott's disease by the straightening of the vertebral column, was advocated a few years ago by Dr. Calob of Berek-sur-Mer. This treatment was not, however, accepted by the majority of surgeons, who considered it a most dangerous operation. A recent thesis by Dr. Rogey calls one's attention to

the perils one encounters in carrying out this technic. According to the author the only safe form of treatment is to place the child as early as possible in a well-made plaster apparatus.

#### A New Treatment of Whooping Cough.

A French physician, Dr. de Lamallere, has been using in the treatment of whooping cough the inhalation of formic acid vapors. All that is required is to burn a pastille of formol on an alcohol lamp every hour. In one to three days the vomiting stops, as well as the fits of coughing. The latter are reduced to two or three in the twenty-four hours. Out of 22 cases Dr. de Lamallere has had two failures, four tardy results, and 18 complete cures in eight days, the convalescence being included in this period. The treatment should, however, be applied in the first eight days, and the patient should be kept in the same room during the whole treatment.

#### Action for Malpractice Non-Suited.

A well-known surgeon of Amiens has just been prosecuted for malpractice by the parents of a young woman on whom he operated two years ago. The parents accused the doctor of having left a compress in the abdomen after having performed laparotomy and pretended that the death of the patient, which took place eleven months afterward, was due to this error in the treatment. No clear proof of this could be furnished by the parents of the young woman, and they were condemned to pay 1000 francs damages.

## Correspondence.

### Voluntary National Examining Board.

WHEELERSBURG, OHIO, May 12, 1902.

*To the Editor:*—The proposed organization of a national medical examining board as outlined by THE JOURNAL, January 11, page 108, and advocated in the last number by Dr. W. L. Rodman, Philadelphia, is a move in the right direction, and to my mind offers the best practical plan yet suggested for overcoming the abuses which the best elements of the profession would gladly see abolished.

With regard to the compensation of the proposed board, about which there seem to be divergent views, I wish to inquire why it might not be feasible to obtain recognition from the trustees of the great Carnegie Institution whose objects, in addition to the promotion of research, are declared to be "to encourage the application of knowledge to the improvement of mankind; to conduct, endow and assist investigation in any department of scientific literature or art, and to this end to co-operate with governments, universities, colleges, technical schools, learned societies and individuals."

Is not the avowed scope of this institution as here set forth by the trustees, as well as in the proclamation of its distinguished founder, sufficiently broad to admit of entering into legitimate relations in harmony with its declared purposes, with such a board as it is now in contemplation to create? Is there any other use to which the immense resources of the institution could be applied that would so stimulate the advancement of practical science, and indirectly promote original research, as an affiliation and co-operation with a board especially designed to uplift the qualifications of the most learned of the professions? Would not the board itself derive additional consideration and authority by reason of its connection with this unique institution—thus insuring permanency, independent action and universal recognition, commensurate with its own high character and its distinguished association?

In this event would the board need to limit its action to the bestowal of diplomas of one grade only? Might it not issue certificates of different grades—according to qualifications—just as the licensing board in England issues the diploma of M.R.C.S. and also the higher diploma of F.R.C.S.? In this way the advantages of a national certificate could be secured by a much larger number of physicians, and need not be confined to the young men of the future who, as Dr. Rodman says, are fresh from the colleges and ambitious. Would not the hope of winning the highest distinctions in the power of the board to confer stimulate numbers to engage in the original research who otherwise would have small incentives to lead them on?

JAMES L. TAYLOR.

DETROIT, MICH., May 12, 1902.

*To the Editor:*—I again endorse the idea of a voluntary national examining board. The establishment of such a board and the movement toward interstate reciprocity can go very well in hand, and will probably do so for some time to come.

It is to be hoped that all those who will participate in the meeting of the American Medical Association at Saratoga—especially those who will attend in an official capacity—will study the subjects and become familiar with the various sides of the questions.

Some information may be furnished by the confederation of members of Reciprocating State Medical Examining and Licensing Boards, a meeting of which, as I understand, will take place in Chicago, May 20. Very truly yours,

EMIL AMBERG, M.D.

### Chloroform and Gaslight Again.

CHICAGO, April 30, 1902.

*To the Editor:*—A few days ago a druggist handed me a bottle marked "Squibb's Chloroform" and said that it had been returned to him by a physician, with the statement that it contained so much chlorin that it could not be used for anesthetic purposes. The druggist made inquiry and found that it had been used at night in the presence of an open gaslight. The druggist wished to know whether it contained chlorin or any other injurious impurity. On making the appropriate tests it was found to conform to the pharmacopoeial requirements, containing no free chlorin, no acid or other impurity. I then used some of it to anesthetize a patient for an operation lasting 40 minutes and its effects were all that could be desired of chloroform.

This is written to call attention again to the irritating gas which is formed when the vapor of chloroform comes in contact with a light or a fire. Chloroform is not readily combustible, yet it will burn when the conditions are favorable. The products of this combustion are free chlorin and some very irritating compounds of chlorin, and deaths have been caused by inhaling the mixture so produced at operations where chloroform has been used too freely and without any precautions. All discomfort and danger may be avoided by hanging a towel below the gaslight and keeping the towel moistened with ammonia water throughout the operation. There is no occasion to fill the room with the fumes of ammonia, the amount necessary is small and it is seldom that the operator or his assistants detect its presence. There is little occasion to question the purity of the chloroform and ether at present in the market, and the frequent complaints about impurities in the anesthetics is usually due to ignorance of some such facts as set forth in this communication.

Yours truly,

D. H. GALLOWAY.

## State Boards of Registration.

**In Texas**, next week, the State Board of Medical Examiners expect to be very busy, as 100 candidates are expected.

**The New Jersey Board of Medical Examiners** has examined 87 applicants for medical licenses in the past year; of these, 63 obtained licenses and 24 were refused.

**The California Board** has had a Chinese doctor arrested for practicing without a license. He has done a large business, among both his own countrymen and white persons.

**More Study in Illinois** medical schools is proposed by the board in this state. At the session April 29, in Chicago, a committee proposed the extension of the time required for medical study to eight months in each of four years.

**The Pennsylvania Medical Examining Board** met in Harrisburg April 1. In organizing, Dr. Henry Beates, Jr., Philadelphia, was made president, and Dr. H. S. McConnell, New Brighton, secretary. The next examination will be held June 25-28, simultaneously in Pittsburg, at the Central High School, and in Philadelphia, in Industrial Hall.

**The Tennessee Medical Examiners** held simultaneous examinations at Nashville, Memphis and Knoxville, April 1 and 2. The number of questions was 64, on 8 subjects, 60 per cent.

being required for temporary license and 75 per cent. for permanent. Of 49 candidates, 38 passed and 11 failed. Of 34 non-graduates, 8 successfully applied for temporary license and 17 for permanent; 6 desired permanent license, but were only able to attain a grade entitling them to temporary license; 3 were rejected absolutely. Of the 15 graduates, one from the Georgia College of Eclectic Medicine and Surgery was granted temporary license, not being able to pass 75 per cent., and one was rejected absolutely. The remainder, numbering 13, were given permanent license and are enumerated as follows:

| Candi. Sch. of date. Pract. | College.                               | Year Grad. | Per cent. |
|-----------------------------|--|------------|-----------|
| 34 R.                       | University of Georgia.....             | 1901       | 84        |
| 49 R.                       | Medico-Chir. College, Philadelphia.... | 1901       | 97        |
| 53 R.                       | University of Louisville.....          | 1901       | 87        |
| 71 R.                       | Richmond Medical College.....          | 1900       | 82        |
| 81 R.                       | University of Maryland.....            | 1901       | 81        |
| 82 E.                       | Ecl. Med. Inst. of Cincinnati.....     | 1901       | 86        |
| 84 R.                       | University of Virginia.....            | 1896       | 95        |
| 85 R.                       | Missouri Medical College.....          | 1899       | 96        |
| 86 R.                       | University of Maryland.....            | 1899       | 87        |
| 90 R.                       | Tulane University.....                 | 1900       | 92        |
| 92 R.                       | Coll. of Phys. and Surg., N. Y.....    | 1900       | 87        |
| 93 R.                       | New York Polyclinic.....               | 1899       | 92        |
| 98 R.                       | Kentucky School of Medicine.....       | 1898       | 86        |

The Oregon Board of Medical Examiners held its regular semi-annual examination January 7 and 8. The number of subjects was 9, questions 90. The percentage required for passing was 75. There were 17 applicants, all of whom passed. Their percentages are withheld by the board.

## PASSED.

**Kansas Board Will Examine.**—Commencing April 21, all candidates for license to practice medicine and surgery in Kansas will be required to pass a satisfactory examination. No registration will be made on diplomas or on certificates from other state boards. Candidates will not be required to present their diplomas when applying for examination, but they will be required to prove that they have devoted not less than four periods of six months each to medical study, no two of these periods being in the same twelve months. The law requires that osteopaths be registered and licensed to practice osteopathy on presentation of diplomas from accredited schools of osteopathy which have required study for not less than four terms of five months each. The board also provides for granting a temporary license to any student who has completed two or more full courses and who presents a petition from a majority of the practitioners in the county in which he intends to practice, petitioning the board to grant such temporary license. The next examination will be held in Topeka, June 10 and 11. The last examination was held April 17 and 2 out of 10 applicants were able to answer 70 per cent. of the questions. There were 8 subjects for osteopaths and 9 for others.

## Married.

ISAAC F. CRESBY, M.D., Stuart, Iowa, to Miss Marie Bartley of Atlantic, Iowa, May 1.

W. G. MITCHELL, M.D., to Miss Edna Boncher, both of Bismarck, N. Dak., April 30.

GEORGE E. JACKSON, M.D., to Mrs. Josephine E. Reid, both of Chatfield, Minn., April 24.

EDWARD DAWSON, M.D., West Superior, Wis., to Miss Daisy Larkin, of Bay City, Mich., April 30.

JAMES G. BEATTIE, M.D., Preston, Ill., to Miss Lillie Hogue, of Nashville, Ill., at St. Louis, May 1.

ROBERT J. CONWAY, M.D., of Hornellsville, N. Y., to Miss Francis Harriet White, at Buffalo, April 28.

Thomas H. Street, M.D., Alexander City, Ala., to Miss Minnie Lancaster, of Wetumpka, Ala., April 30.

JEFFERSON D. KISER, M.D., Lexington, Ky., to Miss Jennie Butterfield, of Ironton, Ohio, at Covington, Ky., May 2.

ARTHUR A. SMALL, M.D., Toronto, Ont., to Mrs. David L. Barnes, Chicago, daughter of Col. B. J. D. Irwin, U. S. Army, retired, May 12.

## Deaths and Obituaries.

**Zabdiel B. Adams, M.D.** Harvard University Medical School, Boston, 1853, medical examiner for the Eighth Middlesex District, and the oldest practitioner in Framingham, Mass., aged 80, met sudden death, May 1, by a fall over the face of the dam at Southboro. Dr. Adams commenced practice in Roxbury. At the outbreak of the Civil war he volunteered, and was made assistant surgeon of the Seventh Massachusetts, and later was promoted to be surgeon of the Thirty-second Massachusetts Volunteers. He was taken prisoner in 1864, and was confined in Litchburg and in Libby Prison. Soon after his discharge he returned to Boston, but soon moved to Framingham. He was a member of the Framingham and Middlesex County medical societies, and had been medical examiner of the district for twelve years.

**John S. Miller, M.D.** Jefferson Medical College, Philadelphia, 1882, formerly assistant demonstrator of anatomy at Jefferson Medical College, but who was obliged to go to Colorado in 1900 for his health, died in Denver, Colo., April 29, aged 46. Dr. Miller was appointed resident physician at the German Hospital, and subsequently surgeon to St. Joseph's Hospital. He was one of the physicians who went to the relief of Plymouth, Pa., in the typhoid epidemic and to Johnston during the flood. While in Denver he was demonstrator at Gross University. He was a member of the Philadelphia County Medical Society, the State Medical Society, and American Medical Association.

**Lyman Beecher Todd, M.D.** Jefferson Medical College, Philadelphia, 1854, the oldest and most prominent physician of Lexington, Ky., died, May 13, aged 70. After Dr. Todd's graduation he began practice in Lexington, and three years later was elected city physician. From 1861 to 1870 he was postmaster at Lexington, and in 1874 was appointed surgeon to the detachment of United States troops stationed in that city. He was a member of the Lexington and Fayette County medical societies; was treasurer of the Kentucky State Medical Society from 1869 to 1875 and also served a term as president of the society.

**James Francis Finney, M.D.** Tulane University, New Orleans, 1871, prominent as a physician and clubman, ex-

coroner of New Orleans, and quarantine physician under two governors, died at the Hotel Dieu, New Orleans, May 2, from pneumonia, after a short illness, aged 53. During the yellow fever epidemic in 1873 he was one of the corps of physicians who volunteered their services and worked heroically to save the lives of their fellow citizens.

**Thomas Dudley Isom, M.D.** Jefferson Medical College, Philadelphia, 1839, and a resident of Oxford, Miss., since his graduation, died at his home, May 4, from heart failure, after a very short illness, aged 86. He was a delegate to the secessional convention in 1860, and served as a surgeon throughout the Civil war. He was first president of the Confederate hospital, Richmond, and afterward was president of the hospital at Columbus.

**Cyrus D. Hottenstein, M.D.** Jefferson Medical College, Philadelphia, 1848, for more than twenty years physician to the Working Home for the Blind, West Philadelphia, surgeon and chief surgeon of the Third Division, First Army Corps, throughout the Civil war, and thereafter a practitioner of West Philadelphia, and surgeon to the Pennsylvania Railroad, died at his home, May 1.

**William S. Loomis, M.D.** University of Michigan, Ann Arbor, 1895, died at Manila, April 30, from intermittent fever, after a short illness, aged 33. Dr. Loomis formerly practiced in Ann Arbor, Mich., but went to the Philippine Islands in December, 1900, and was in charge of a large hospital there. Tropical heat and overwork are said to be responsible for his fatal illness.

**Charles W. Marvin, M.D.** Western Reserve University, Cleveland, Ohio, 1851, the pioneer medical man of Ithaca, Mich., where he located in 1860; assistant surgeon of the Twenty-sixth Michigan Volunteer Infantry, and later a trustee and director of the school board, died at his home in Newark, Mich., April 27, after a long illness, aged 78.

**D'Estaing Dickerson, M.D.** Albany (N. Y.) Medical College, 1857, the wealthiest physician of Kansas City, Mo., a veteran of the Civil war, through which he served, being discharged as chief surgeon of the Sixth Army Corps, died from pneumonia, at his home in Kansas City, May 3, after a short illness, aged 67.

**Joseph A. Tarkington, M.D.** University of Georgetown, Washington, D. C., 1870, who practiced for thirty years in Washington, D. C., and was then obliged to retire on account of ill-health to the family homestead near Greensburg, Ind., died there May 1, aged 64.

**Maximilian A. Cachot, M.D.** Cooper Medical College, San Francisco, 1864, a native of France, but a resident of San Francisco for nearly forty years, died at his office in that city from apoplexy, after a few hours' illness, April 29, aged 68.

**Edward Lawrence Feehan, M.D.** Washington University, St. Louis, 1861, brother of Archbishop Feehan of Chicago, and for forty years a practitioner of St. Louis, died at his home in that city, May 8, from Bright's disease, aged 67.

**Harvey W. Curtiss, M.D.** Western Reserve University, Cleveland, 1852, a practitioner of Chagrin Falls, Ohio, for fifty years, a state senator, and once acting lieutenant-governor of the state, died at his home, April 30, aged 78.

**John Homans, II, M.D.** Harvard University Medical School, Boston, 1882, a member of the Papyrus Club and of the State Medical Society, died at his home in Boston, after a brief illness, May 4, aged 45.

**Charles McDonough, M.D.** Pennsylvania Medical College, Philadelphia, 1848, who had practiced in Reading for fifty-five years, and was a veteran of the Civil war, died recently at his home in Reading, aged 75.

**John T. Shutt, M.D.** College of Physicians and Surgeons, Baltimore, 1880, a charter member of the Mercer County (Pa.) Medical Society, died suddenly from neuralgia of the heart, May 4, aged 50.

**William D. Karns, M.D.** College of Physicians and Surgeons, Keokuk, Iowa, 1878, a practitioner of Dahlgren, Ill., for nearly twenty-five years, died at his home in that place, April 26, aged 58.

**Charles H. Masten, M.D.** Bellevue Hospital Medical College, New York, 1867, died at his home in Nyack, N. Y., May 1, from pneumonia, after an illness of ten days, aged 62.

**F. Antes Canfield, M.D.** Rush Medical College, Chicago, 1872, the pioneer physician of Juneau County, Wis., died at his home in Necedah, April 22, aged 71.

**Henry D. Green, M.D.** Medical College of the State of South Carolina, Charleston, 1850, died after a prolonged illness at Donalds, S. C., April 29.

**Ulric D. Stone, M.D.** Omaha (Neb.) Medical College, 1892, died at his home in Steinauer, Neb., April 18, from neuralgia of the heart, aged 38.

**William E. Byrd, M.D.** died from pneumonia, after a short illness, at his home in Montrose, W. Va., April 30, aged 64.

**John M. Eye, M.D.** University of Michigan, Ann Arbor, 1863, died recently at his home in Canton, Ohio.

## Association News.

### Railroad Rates for Saratoga Meeting.

The Committee on Transportation reports that a rate of one and one-third on the certificate plan will now apply throughout the entire United States, all the passenger associations having agreed to the same. This rate has been extended to include the meeting of the American Academy of Medicine, which meets at Saratoga, June 7. The return limit is June 17 without extra fee and July 2 on payment of fifty cents. All going tickets must be accompanied by a certificate and, in order to receive reduction returning, certificates must be signed by Dr. William E. Swan, Saratoga, between June 11 and 13. In order to secure the privilege of time extension between June 16 and July 2, all certificates must be signed as above and deposited with the local ticket agent not later than June 17. Failure to comply with any of these requirements will result in forfeit of time extension limit and reduced rate returning. In order to avoid delay and extra cost of baggage transfer across New York City, delegates and members from the southeastern territory, and that of the trunk line south of New York City will find it convenient to purchase tickets direct over the Pennsylvania lines or other roads connecting with the West Shore Railroad at Jersey City going direct through to Albany or Saratoga. For those in the central and extreme western and southwestern territories, the most direct and continuous routes will be via the Chicago, Milwaukee & St. Paul and Big Four connections by way of the Lake Shore & Michigan Southern Railway, all of which run direct to Saratoga via Buffalo and Albany over the New York Central and Delaware & Hudson Road. Any of the passenger and ticket agents of the roads herein enumerated will furnish special information to delegates in the matter of time, trains, and return certificates.

H. L. E. JOHNSON, M.D., Chairman.

Committee on Transportation.

### Special Report of the Committee on National Legislation.

The Committee on National Legislation reports that the bill proposed by them to promote and honor the ex-president of the American Medical Association, Surgeon-General George M. Sternberg, was introduced in the Senate by Senator Gallinger April 12. The Bill is known as Senate 5213 and reads: "A Bill providing for the selection and retirement of medical officers in the Army. Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the President of the United States is hereby authorized to select one from such medical officers of the Army as have served forty-one years or more, nine years of which shall have been as Surgeon-General, and by and with the advice and consent of the Senate, appoint him a major-general of the United States Army, for the purpose of placing him on the retired list."

On May 7 Senator Joseph R. Hawley, Chairman of the Senate Committee on Military Affairs, reported the bill favorably and recommended its passage. His report includes letters from the Secretary of War addressed to the House of Representatives, from the Adjutant-General, from the Surgeon-General, and others. The report also gives many details in regard to Surgeon-General Sternberg, showing what he has accomplished, the honors that have been conferred on him, together with a list of his contributions to medical literature previous to 1893. The report is very flattering to General Sternberg.

## Miscellany.

**The Fee-Splitters.**—The abominable practice of fee-splitting must come to an end. The fellow who auctioneers his patients off to the surgeon and specialist—to the highest bidder—has had his day, and will as surely receive his just deserts as time lasts. At the next meeting of the American Medical Association there can be no doubt but what that great body will take such action as will force every one of the fee-splitters to abandon the abominable practice or be expelled from any medical society that they may then belong to, and will bar them from entering any medical societies in the future. There can be no way of evading the punishment that is in sight for them; it is inevitable.—*Amer. Practitioner and News.*

**Hospital Statistics.**—*American Medicine* makes some interesting observations on the figures published by the State Board of Charities bearing on the number of in-patients at a particular institution therein referred to. It is stated that during the year 1900 this hospital admitted no less than 9308 new patients. Now, the total bed accommodation for patients in that institution happens to be 292, and the average number of beds occupied during the year was 194. Taking the average stay in hospital of each patient to be eighteen days, an estimate which some pains have been taken to verify, the figures seem to show that at least 5636 persons must have slept two in a bed; indeed, if instead of the total bed capacity, we take the average of bed days, as reported, it will be seen that a large number of patients must have slept three in a bed! Our contemporary naturally asks how this can have come to pass and suggests the following alternative explanations—either the average stay in hospital must have been less than eighteen days, although in other hospitals the average varied from twelve to twenty-one days, or the figures must have been falsified in order to influence the allocation of State funds. As the latter hypothesis is, of course, inadmissible we are thrown back upon the supposition that several persons must have slept in a bed. If so it may be remarked that disease, like poverty, makes strange bedfellows.—*Med. Press.*

**The Proposed Uniform Organization of State Medical Associations.**—A committee appointed for the purpose by the president of the American Medical Association, consisting of Dr. J. N. McCormack, of Bowling Green, Ky., Dr. P. Maxwell Foshay, of Cleveland, and Dr. George H. Simmons, of Chicago, has devised a form of constitution and by-laws intended to serve as the substance of the constitution and by-laws of each State organization affiliated or to be affiliated with the national association, and the plan is set forth in a report published in the association's JOURNAL for May 3d. The gentlemen of the committee do not profess that their device is perfect or that in all its details it will be found available to advantage in every State; indeed, they intimate that much of the wording of those portions that in all probability will prove acceptable in all the States need not be formally enacted, inasmuch as it is elucidative rather than declaratory. It is desirable to have the constitution and by-laws of any society as brief and condensed as may be consistent with clearness, but in this instance we think the entire report of the committee should be preserved in the archives of every State society that adopts its fundamentals, for it will furnish the readiest means of expounding the enactments.

Recognizing the diversity of conditions in the various parts of such an enormous country as this, the committee has wisely aimed at flexibility in all but essentials, and has sought to provide the greatest facility for conciliation and compromise in regard to disagreements and friction of all sorts and for the utmost liberality in rating individual physicians as to their eligibility to membership in the component county societies, which membership carries with it the right of representation in the State organization and in the American Medical Association. There is, indeed, so far as we can see, no reason why, under such a general scheme as the committee has devised, there should not shortly be achieved a close approach to such an ideal unification of the medical profession as was lately forecast by Dr. Charles A. L. Reed, of Cincinnati, in his remarks before a Dayton society, published in our issue for

April 19, for no reputable legally qualified practitioner would be kept out of a county society or debarred from acting as its representative in the State and national organizations. no matter what his therapeutical theories or practice might be—provided only he renounced sectarianism, which would not at all mean that he should give up his belief or cease to practice in accordance with it, but only that he should no longer exploit it with the laity. Only as a united profession can we readily influence legislation in the interest of the public health and for the advancement of medical science, and we believe that the great body of physicians throughout the Union will concur in the liberality shown by the committee, and feel thankful to the gentlemen composing that body for the assiduity and broad-mindedness which they have brought to the devising of their scheme.—*N. Y. Med. Jour.*

**A Training School for Nurses in Turkey.**—The great scarcity of nurses in Turkey has led to a proposal, made by the authorities of the American College for Girls in Constantinople to its trustees in Boston, that in connection with the academic course a medical department in the form of a hospital and training school for nurses should be established. It is urged that there is a splendid opening for nurses in taking charge of the native women, who lead idle, aimless lives, and take very little air or exercise, and who consequently develop many real or imaginary diseases. These women greatly need someone to instruct them in the simple laws of hygiene and the care of the body, and nurses would be heartily welcomed by them. The Turkish hospitals import their nurses from Germany.—*Brit. Med. Jour.*

## Societies.

### COMING MEETINGS.

American Medical Association, Saratoga Springs, N. Y., June 10 to 13.

Illinois State Medical Society, Quincy, May 20-22, 1902.  
Medical Association of the State of Missouri, St. Joseph, May 20-22, 1902.

Arizona Medical Association, Tucson, May 21-22, 1902.  
Medical Association of Montana, Anaconda, May 21-22, 1902.  
Medical Society of West Virginia, Parkersburg, May 21-23, 1902.  
Iowa State Medical Society, Des Moines, May 21-23, 1902.  
Indiana State Medical Society, Evansville, May 22-23, 1902.  
American Pediatric Society, Boston, May 26-28, 1902.  
American Laryngological Association, Boston, Mass., May 26-28, 1902.

American Gynecological Society, Atlantic City, May 27, 1902.  
Connecticut Medical Society, New Haven, May 28-29, 1902.  
Ohio State Medical Society, Toledo, May 28-30, 1902.  
American Laryngological, Rhinological and Otolological Society, Washington, D. C., June 2-4, 1902.

American Surgical Association, Albany, N. Y., June 3-5, 1902.  
Louisiana State Medical Society, Shreveport, June 3-5, 1902.  
Maine Medical Association, Portland, June 4-6, 1902.  
South Dakota State Medical Society, Scotland, June 4-5, 1902.  
Wisconsin State Medical Society, Milwaukee, June 4-6, 1902.  
Rhode Island Medical Society, Providence, June 5, 1902.  
Association of Military Surgeons of the United States, Washington, D. C., June 5-7, 1902.

American Orthopedic Association, Philadelphia, Pa., June 5-7, 1902.

American Academy of Medicine, Saratoga Springs, N. Y., June 7, 1902.

American Association of Life Insurance Examining Surgeons, Saratoga Springs, June 9, 1902.

National Confederation State Medical Examining and Licensing Boards, Saratoga Springs, N. Y., June 9, 1902.

Association of American Medical Colleges, Saratoga Springs, N. Y., June 9, 1902.

American Climatological Association, Los Angeles, Cal., June 9-11, 1902.

American Proctological Association, Saratoga Springs, N. Y., June 10, 1902.

Medical Society of Delaware, Newark, June 10, 1902.

Massachusetts Medical Society, Boston, Mass., June 10-11, 1902.

Medical Society of the State of North Carolina, Wilmington, June 10-14, 1902.

Colorado State Medical Society, Pueblo, June 17, 1902.

American Medico-Psychological Association, Montreal, June 17-20, 1902.

Minnesota State Medical Society, Minneapolis, June 18, 1902.

Medical Society of New Jersey, Atlantic City, June 24-26, 1902.

Washington State Medical Society, Tacoma, June 24-26, 1902.

Michigan State Medical Society, Port Huron, June 26-27, 1902.

**Detroit Physicians' Association.**—At the annual meeting of this Association, April 28, Dr. Daniel Kerr was elected president and Dr. Walter J. Cree, secretary. The Association now numbers nearly 300.

**Austin (Texas) Academy of Medicine.**—At a recent meeting of the Academy, Dr. Matthew M. Smith was elected presi-

dent; Dr. Joseph S. Wooten, vice-president; and Dr. W. Allen Harper, secretary and treasurer.

**Pike County (Ill.) Medical Society.**—At the annual meeting of this Society, held in Pittsfield, April 24, Dr. Henry T. Duffield, Pittsfield, was elected president; Dr. Francis M. Crane, Pittsfield, vice-president, and Dr. Rufus H. Main, Barry, secretary.

**American Orthopedic Association.**—This Association will meet at Hotel Walton, Philadelphia, June 5, 6 and 7. A feature of the meeting will be an evening with the plaster-of-paris bandage in the amphitheater of Jefferson Medical College Hospital, June 6.

**Barry and Eaton (Mich.) Medical Association.**—At the annual meeting of this Society, held in Nashville, April 24, Dr. Aleck F. Hutchinson, Nashville, was elected president; Dr. Arthur E. West, Eaton Rapids, vice-president, and Dr. F. F. Shilling, Nashville, secretary and treasurer.

**Lewis and Clark County (Mont.) Medical Society.**—A number of physicians of Helena met, April 30, and reorganized this Society, which disbanded in 1894, with an initial membership of eight. Dr. George W. King was elected president; Dr. Benjamin C. Brooke, secretary, and Dr. Rudolph Horsky, treasurer.

**Charity Hospital (New Orleans) Alumni.**—The internes and ex-internes of Charity Hospital met and banqueted, April 30. Dr. E. Denegre Martin, New Orleans, was elected president; Dr. John J. Laurans, New Orleans, vice-president; Dr. S. M. D. Clark, New Orleans, secretary, and Dr. Jules Lazard, New Orleans, treasurer.

**Linn County (Mo.) Medical Society.**—At the annual meeting of this Society, held in Laclede, April 29, the following officers were elected: Dr. F. W. Burke, Laclede, president; Drs. Emanuel S. Wenger, Brookfield, and Urbane C. Dryden, Shafter, vice-presidents; Dr. Edmond D. Standly, Linneus, secretary, and Dr. John L. Burke, Laclede, treasurer.

**Central Medical College (St. Joseph, Mo.) Alumni Association.**—On April 28 this Association elected the following officers: Dr. Louis J. Dandurant, St. Joseph, president; Drs. H. A. Green and F. Austin Patterson, St. Joseph, vice-presidents; Dr. Herbert Lee, secretary; Dr. Grace M. Bliss, corresponding secretary, and Dr. A. D. Pope, treasurer.

**Central Illinois Medical Association.**—The twenty-eighth annual meeting of this body was held at Pana, April 29. The following officers were elected: Dr. Everett J. Brown, Deatur, president; Drs. John H. Miller and George W. Fringer, Pana, vice-presidents; Dr. John N. Nelms, Taylorville, treasurer, and Dr. Frederick J. Eberspacher, Pana, secretary.

**North East Missouri Medical Association.**—This Society held a session in Memphis, April 8 and 9. The following officers were elected: President, Dr. Robert B. Turner, Canton; vice-president, Dr. Frank B. Hiller, Kahoka; secretary, Dr. E. E. Parrish, Memphis, and treasurer, Dr. James B. Bridges, Downing. The next meeting to be held at Kahoka, October 14.

**Berkshire District (Mass.) Medical Society.**—At the annual meeting, held in Pittsfield, April 24, this Society elected Dr. Stephen C. Burton, Pittsfield, president; Dr. Lucius T. Ingham, West Stockbridge, vice-president; Dr. Lawrence C. Swift, Pittsfield, secretary; Dr. William Le R. Paddock, Pittsfield, treasurer, and Dr. William W. Leavitt, Pittsfield, librarian.

**State Association of Colored Physicians of Florida.**—The colored practitioners of Florida met at Fernandina, April 24, and organized this Association, with Dr. Percy N. Richardson, Fernandina, president; Dr. A. L. Pierce, Orlando, vice-president; Dr. W. C. Smalls, Jacksonville, secretary, and Dr. A. S. Jerry, Tallahassee, treasurer. The next meeting will be held in St. Augustine in May, 1903.

**Ohio Valley Medical Association.**—The seventh semi-annual meeting of this Association was held in Owensboro, Ky., May 1 and 2. The following officers were elected: Dr. T. Atchison Frazer, Marion, Ky., president; Drs. A. M. Hayden, Evansville, Ind., and Daniel M. Griffith, Owensboro, Ky., and Campbell H. Johnson, Henderson, Ky., vice presidents, and Dr. Dudley S. Reynolds, Louisville, librarian.

**Addison County (Vt.) Medical Society.**—This Society, which was organized in 1813, but which had not held a meeting for 22 years, is to be reorganized. In response to a call of Dr. James M. Hamilton, Rutland, nine physicians met at Middlebury, April 29. Dr. Edward P. Russell, Middlebury, was made

chairman, and Dr. Merritt H. Eddy, Middlebury, secretary. A committee on reorganization, constitution and by-laws was appointed to report in June.

**College of Physicians and Surgeons, Baltimore, Alumni Association.**—This Association held its annual business meeting and banquet, April 28. The following officers were elected: Dr. Samuel H. Allen, Provo City, Utah, president; Drs. Charles F. Blake, Baltimore, and Thomas A. Connell, Easton, Md., vice-presidents; Dr. Hubert C. Knapp, Baltimore, secretary; Dr. C. W. G. Rohrer, Baltimore, assistant secretary, and Dr. Charles E. Brack, Jr., Baltimore, treasurer.

**University of Buffalo Medical Department Alumni Association.**—At the annual meeting of the alumni of this institution, held at Buffalo, May 2, the following officers were elected: Dr. Alfred W. Bayliss, Buffalo, president; Drs. Alfred W. Henckell, Rochester; Fridolin Thoma, Buffalo; Henry S. Benham, Honeoye Falls; Jane W. Carroll, Buffalo, and George A. Himmelsbach, Buffalo, vice-presidents; Dr. Thomas H. McKee, Buffalo, secretary, and Dr. Herman K. De Groat, Buffalo, treasurer.

**Clark County (Ohio) Medical Society.**—The first meeting of the newly-consolidated Clark County Medical Society and Springfield Academy of Medicine was held at Springfield, May 5. The following officers were chosen for the new society: Dr. Read L. Bell, president; Drs. John P. Dugan, and Noah Myers, vice-presidents; Dr. J. C. Easton, secretary, and Dr. D. Walter Spence, treasurer, all of Springfield. Drs. Isaac Kay, John H. Rodgers and Henry H. Seys, Springfield, each of whom had practiced medicine for more than fifty years, were made emeritus members.

**International Association of Railway Surgeons.**—The fifteenth annual meeting of this Association was held in St. Louis, Mo., April 30, May 1 and 2, under the presidency of Dr. Rhett Goode, Mobile, Ala. The following officers were elected for the ensuing year: President, Dr. William A. McCandless, St. Louis; vice-presidents, Drs. Arthur L. Wright, Carroll, Iowa; John B. Rule, St. Louis; John C. Wyso, Norfolk, Va.; E. E. Kitchener, Canada; William G. Jameson, Palestine, Texas; Reyes M. Ortego, City of Mexico, and Philander Daugherty, Junction City, Kansas. Drs. David S. Fairchild, Clinton, Iowa; A. I. Bouffleur, Chicago, and Joseph R. Hollowbush, Rock Island, Ill., were elected members of the executive board. Drs. Louis J. Mitchell, Chicago, and James A. Duncan, Toledo, Ohio, were re-elected secretary and treasurer, respectively. Indianapolis, Ind., was selected as the place for holding the next annual meeting.

## CHICAGO LARYNGOLOGICAL AND CLIMATOLOGICAL ASSOCIATION.

*Regular Meeting, held April 21, 1902.*

The President, Dr. Moreau R. Brown, in the Chair.

### Congenital Heart Disease.

DR. JOHN EDWIN RHODES reported a case of probable congenital heart disease in a girl of 11. Her mother and father are living. They have had 8 other children: all are living and well, except one who died of hip disease from an injury. She weighs 60 pounds; is well nourished, lips red, skin of a healthy normal color and temperature normal. She had röteln when she was 3 years of age, followed by double pneumonia and she has had several attacks of pneumonia since. She has never had rheumatism. Her mother says that she was never as strong as her other children, but she gives no history of cyanosis at birth or subsequently, although she says that her color was not as good as that of the other children. The child says that as long as she can remember she has been somewhat short of breath on exertion, as in walking fast or going upstairs, but it seems to be no worse now than it has been for some years past. There is no pain or tenderness over the chest. She often has palpitation when tired or excited, the heart's action then being much accelerated. I found her pulse 104, rather weak, but regular, respirations 22; temperature is usually normal. Her blood count shows 5,300,000 red corpuscles, white 17,000. The tongue is clean; the appetite and digestion good, and the bowels regular.

There is no cyanosis, except a slight duskiess of the finger

nails, and no clubbing of the fingers. The impulse of the heart's apex is in the fifth intercostal space, half inch outside of the mamillary line, and is about 1 inch in diameter. An impulse is also seen at the base of the left border of the sternum in the third intercostal space. No thrill is felt over the apex. Over the upper portion of the precordia as far out, on the left side, as the anterior axillary line in the second and third intercostal spaces and with diminishing force as high as the clavicle, a thrill is felt. Its maximum intensity is in the second intercostal space two inches from the median line. The thrill is not perceptible to the right of the sternum. There is no bulging of the precordia. Dulness on the left side begins at the first rib and extends downward to the sixth. Dulness to the right extends 1½ inches from mid-sternal line in third and fourth interspaces. Dulness to the left extends 1½ inches from mid-sternum in first interspace, 2½ inches from mid-sternal line in second and third interspaces, 3 inches in the fourth interspace, and 3½ in the fifth. On auscultation at the apex there is no distinct murmur but a slight systolic roughness which is not transmitted. Over the base of the heart a loud diastolic and a systolic murmur are heard distinctly in

the pulmonary area and very distinctly at the left border of the sternum in the second and third intercostal spaces, the systolic murmur being more distinct in the second intercostal space about 2 in. to left of sternum. These murmurs are not apparently transmitted to the arteries of the neck nor are they heard behind. The second pulmonic sound is very markedly accentuated. There is no accentuation of the second sound in the aortic area nor are there murmurs in this area. No venous hum is heard at the base of the neck. There are no evidences of tumor in the pulmonary area.

In this case we probably have an obstruction and insufficiency at the pulmonary orifice with hypertrophy and dilatation of the right ventricle. There is probably also a hypertrophy of the left ventricle and dilatation and hypertrophy of the left auricle with intra-pulmonary obstruction to account for the accentuation in the second pulmonic sound.

### A Case of Aneurysm of the Aorta of About Forty Years' Duration.

DR. RHODES also presented this case: Mrs. W. H. S., aged 50, married. Her maternal grandfather had rheumatism; some second cousins of the mother died of phthisis. She had scarlet

fever and measles in childhood. She never had rheumatism or other illness of importance. She is of medium height, weighing 148 pounds; five years ago her weight was 185. She has never had children or miscarriages. Her pulse is 86; that at the left wrist being somewhat stronger than that at the right. Her strength at the present time is not very good. She has frequent headaches and an occasional slight edema of the ankle. She has dyspnea on slight exertion and is occasionally conscious of shortness of breath when quiet. She has been able for years, however, to go about her ordinary duties without much difficulty; of late, she has suffered somewhat more than usual from dyspnea on exertion, as in putting coal in the furnace. The respirations are not much accelerated; appetite is good, digestion not good; the bowels are regular. She complains of occasional very marked throbbing of the arteries all over the body. She is complaining of numbness lately in the back part of the throat and tongue and occasionally suffers from palpitation after eating. She states that when she was a child she was in the habit of jumping a rope to great excess and to this over-exertion she attributes her trouble. She knows that she has had this affection of her chest for 40 years. Over 21 years ago she was seen by Dr. Austin Flint, Sr., Dr. Janeway and others in New York and a diagnosis was made of aneurysm of the aorta and she was shown to the students in classes at Bellevue and elsewhere.

On examination of the chest, we find on the first interspace on the right no dulness. On the left side there is normal resonance and no bulging. There is slight bulging over the sternum at the second rib more marked to the right than to the left. At the second rib there is dulness one inch to the right of the sternum, third rib 2 inches, fourth rib 1 inch, at which latter point there is some tenderness. A thrill is felt in the second interspace on the right over which area pulsation is felt and seen. The thrill is felt 2 inches to the right of the sternum and about  $\frac{1}{2}$  inch farther to the right than the area of actual dulness. The apex is in its normal position. On auscultation a loud systolic murmur is heard all over the left side of the chest, increasing in intensity into the aortic area. In the aortic area, systolic and diastolic murmurs are heard and a systolic shock is present. The systolic murmur is loud over the upper part of the chest, but more marked in the second and third intercostal spaces of the right side. This murmur is also heard over the carotid and behind at the right side of the spine from the apex to the fourth dorsal vertebra. An interesting feature of this case is that the patient has been able to pursue her usual avocations for about 40 years and there has evidently been very little increase, if any, in the size of the aneurysm, and she has suffered very little from such symptoms as one with such a lesion might ordinarily be expected to have.

DR. WILLIAM E. CASSELBERRY—I am a little surprised, if it be an obstructive lesion of the pulmonary orifice, that there should not be disclosed more hypertrophy of the right ventricle.

DR. E. FLETCHER INGALS—In the case of the little girl there is no way of telling the exact condition which causes the signs. The history and the systolic murmur at the base of the heart is indicative of a communication between the auricles or ventricles; yet the character of the murmur and the sudden sharp closure of the pulmonary valves would indicate that the sound is produced at the pulmonary orifice.

DR. A. M. COWIN—The case of the little girl is one of those interesting instances of heart lesion, the signs of which are seemingly at variance with the rules in our text-books and about which it is unsafe to dogmatize. The absence of aortic regurgitation, and of all the classical signs and symptoms of that affection, would rule out aortic leakage as a cause of this diastolic murmur. The murmur is more of the type of that produced by mitral obstruction in some respects, but unlike the usual obstructive murmur in that it lasts seemingly throughout diastole. The supposition of mitral obstruction is strengthened by the accentuated pulmonic sound and the clear and loud mitral first sound, and also by the enlarged left auricle. The signs of tricuspid obstruction, which is a rare affection, are absent in this patient.

DR. RHODES (closing the discussion)—In making a diagnosis of pulmonary obstruction and regurgitation, I have done so largely by exclusion. If we had a diastolic murmur at the mitral valves, it would be apt to be a presystolic murmur at the latter part of the diastole and be heard distinctly in the mitral area. The thrill of mitral stenosis is presystolic. A tricuspid diastolic murmur would have the same time and rhythm as the mitral and it would be apt to be a presystolic murmur. We would have epigastric pulsation. But there is no such evidence here. The right side of the heart is enlarged, but not markedly so. It is an anomalous condition, and we can not say that the only lesion is located at the pulmonary valve.

In the determination of the question as to whether the lesions were congenital or acquired, I have arrived at the decision of congenital disease from the fact that congenital lesions at this valve are not uncommon, and the right side of the heart is the one usually involved. Pulmonary obstruction is usually accompanied by incompetency in congenital disease. It would be a most unusual occurrence to have these valves selected for involvement in an acquired endocarditis. It is quite possible, I suppose, that the attack of German measles may have caused further disease in an already crippled heart and the condition of the left auricle and ventricle may have dated from that time.

(To be continued.)

#### ASSOCIATION OF AMERICAN PHYSICIANS.

*Seventeenth Annual Meeting, held in Washington, D. C., April 29 and 30, 1902.*

President, Dr. J. C. Wilson, Philadelphia, in the Chair.

#### Presidential Address.

DR. WILSON referred to the early history of medical organization in this country, the beginning being far back. Two organizations, one in Boston and one in New York, both short-lived, preceded the oldest existing medical society in this country, the Litchfield County Medical Society of Connecticut, which was founded in 1765 and is still flourishing. After this, societies were formed in New Jersey, Massachusetts, Philadelphia and finally in 1847 the American Medical Association came into being.

He stated that the services rendered to the profession, and through the profession to the people, by this great Association, with its constituent state and county societies, could not be overestimated. "It has brought the profession together and given it solidity. It has not only encouraged the formation and growth of local societies, but has proved a constant stimulus to activity on their part. It has, by means of its section work and excellent journal, set a high standard of professional attainments and fostered among physicians a deep sense of responsibility and a lofty conception of the duties and privileges of their calling."

The address closed with tributes of respect to the members who have died during the past year, including Drs. John T. Metcalf, who was chosen an honorary member when the society was first organized; Meredith Clymer and William Waring Johnston, an original member of the association, for many years its treasurer and at the time of his death a member of the council.

An amendment to the Constitution providing for the increase of the possible membership to a hundred and fifty was introduced, and, under the rules, laid over for a year.

#### Comparative Toxicity of Ammonium Compounds—A Study in Auto-Intoxication.

The scientific programme was then taken up and the first paper presented by Dr. B. K. Rachford on the above subject. He had studied the comparative toxicity in mice of such salts as may be formed by the union of ammonium, potassium, sodium, calcium and magnesium with such acid ions as may be present in the body in health and disease. From these experiments he drew the same conclusions as those which he expressed before this society three years ago, that the xanthin bodies were the important toxic principles, but that their toxicity was increased by small quantities of ammonia in combination with them. The ammonium compounds of the xanthin

bodies are toxic agents in producing migraine and other lithemic disorders which he described in his previous papers as being due to xanthin bodies alone. This point seems plausible when one remembers that the functionally incompetent liver, which is an important etiologic factor in all these conditions, may by the fall of its urea-forming function throw into the general circulation sufficient ammonia and uric acid leucemains to combine and in this way diminish the excretion of urea and increase the excretion of ammonia and xanthin bodies.

#### **An Estimate of the Amount of Toxin in the Blood of a Horse Infected with Tetanus.**

DR. B. MEADE BOLTON referred to the outbreak of tetanus in St. Louis last year which was shown to be due to the use of diphtheria antitoxin which contained tetanus toxin. The antitoxin used in those cases was obtained from a horse that exhibited symptoms of tetanus two days after the blood was drawn and he was able to demonstrate the presence of a considerable amount of toxin in this serum. There is no evidence in literature of such a finding having been made previously under similar circumstances. All the known facts before have seemed to show that the toxin in some cases, whether it was injected into the blood or developed in the tissues from infection, disappeared from the blood, while in other cases even though a minute quantity had been used it could be found in the blood. In experimental work it was found that the toxin remains circulating in the blood in guinea-pigs while in rabbits it disappears from the blood and combines with the tissues. Dr. Bolton's work consisted in inoculating horses with garden work known to contain the tetanus organism by the result of tests upon small animals and also by inoculating one horse with a culture that produced tetanus in smaller animals. The blood from all the horses was drawn at intervals of twenty-four hours after inoculation and the amount of toxin in the serum determined by the injection of guinea-pigs and other small animals. It was shown that the toxin makes its appearance in the blood of the horse several days before any symptoms of tetanus are to be observed and that it gradually increases until about two days before the symptoms become noticeable, after which it rather suddenly diminishes and even disappears in some cases. The amount of toxin varies considerable in different cases.

#### **Pseudo-Tubercle Bacilli.**

DR. A. C. ABBOTT read a paper on "The Etiologic Significance of the Acid-Resisting Group of Bacteria and the Evidence of Their Mechanical Relationship to the Bacillus of Tuberculosis." He remarked that it was somewhat disturbing to learn that there exists a group of bacteria that resembles the tubercle bacilli in staining qualities and in appearance. Dr. Abbott and his assistants have conducted an investigation of these organisms, the expenses of which have been borne by the Rockefeller Institute. He gave an account of the methods of investigation and the points of resemblance. He thought that these organisms might be dismissed from consideration in so far as any danger of their causing trouble by infection from milk and butter is concerned. More work has yet to be done to show how closely they are related to the tubercle bacillus. It is shown that they grow as actinomycetes and the work of others has shown that the bacillus tuberculosis under particular methods of inoculation may likewise develop as actinomycetes. These last experiments were confirmed by Dr. Abbott with the tubercle bacillus, an organism being secured that strongly resembles this acid-resisting group.

In discussion, Dr. Flexner said that he had had the privilege of examining Dr. Abbott's specimens and felt that there could be no doubt that the lesions produced by this group of organisms were not true tubercles. The whole lesion studied together reminded one of granulation tissue with a large number of giant cells. He thought the lesions were very similar to those produced by the blastomycetes.

Dr. Meltzer referred to the case of a man who had for many years been considered to be tuberculous, but whose sputum on careful examination showed these peculiar organisms.

#### **The Histologic Alterations of Cytotoxic Intoxication.**

DR. SIMON FLEXNER said the studies of Bordet, Ehrlich, Metchnikoff and others have proven that many kinds of body

cells, when injected into alien animals, give rise to the production of cytotoxins agreeing in many physiologic properties with bacterial and other toxins. He worked particularly with the cytotoxins of the lymphatic organs and found that the lesions produced in the glands are general throughout the body just as they would be after bacterial toxins. The work has some bearing upon the question of terminal infections and shows that in the majority of cases of such infections there is a great reduction of the complement of the circulating blood, if not an entire absence of it.

#### **A Study of Bacterial Cells.**

DR. V. C. VAUGHAN read this paper and referred to the apparatus by which he was able to raise various micro-organisms by the acre and thus secure a sufficient quantity to study chemically their constituents, particularly their pigments. The bacillus prodigiosus has a pigment which is soluble in water and can be used as a stain for cotton, wool or silk goods. Two coloring matters are obtained from this pigment, one yellow and the other beautiful pink, and Dr. Vaughan exhibited some silk handkerchiefs colored therewith.

Subjecting masses of the germs to alcohol he extracted their toxins and evaporating the alcohol obtained a dried powder. Some of these toxins were capable of being split up into two or more forms, for instance, the diphtheria organism produces a soluble toxin against which antitoxin protects, but another toxin is left after the first washing which may or may not be protected against by the antitoxin, and a third toxin is still obtainable from the residue against which antitoxin offers no protection. In all the work of splitting these toxins it was evident that the residues were always less toxic than the whole original substance and if heated further it rapidly lost its toxicity.

#### **On Some Effects of Tobacco on the Tissues of Rabbits**

DR. I. ADLER gave a preliminary report on experiments on rabbits confined within proper limits and fed exclusively on cabbage mixed with an infusion of tobacco. An animal killed after two and a half months shows an enlarged liver, pale and granular, the liver lobulation being very pronounced. The proliferation of fibrous tissue follows the tract of the portal vessels and bile ducts. The liver cells are absolutely normal and the process is restricted entirely to the interstitial tissue. Dr. Adler would not at present attempt to draw an analogy between his findings and a cirrhosis of the liver.

Cases of hematomorphyrinuria after use of sulphonal were reported by Dr. James Tyson and after trial by Drs. Eithington and Starr.

#### **Pneumococcic Arthritis.**

DR. JAMES B. HERRICK stated that this affection was a rare one appearing oftenest during or shortly after croupous pneumonia and most frequently in men. He gave the symptoms and diagnosis. The mortality is 65 per cent. The treatment is immediate incision and drainage.

DRS. OSLER AND MUSSER discussed the subject. In discussion Dr. Osler remarked that one of his assistants had recently worked up this subject carefully and had divided the cases into three groups, one with local symptoms mainly, the second group that follows or is associated with pneumonia and a third group in which the arthritis is associated with a general pneumococcic septicemia. He related the history of one case of the latter kind in which it was difficult to say where the primary lesion was. Blood cultures showed numerous pneumococci as did also aspiration of the joint, and autopsy showed an extensive pneumococcic meningitis, arthritis and general infection of the blood.

DR. MUSSER reported a somewhat similar case with involvement of the joints, beginning with the sterno-clavicular, but the patient finally recovered.

DR. W. T. HOWARD, JR., read a paper on "The Pathology of Herpes Labialis and of Herpes Zoster occurring in an Acute Croupous Pneumonia."

DR. H. F. VICKERY opened the afternoon session by the narration of "A Case of Hodgkin's Disease with Recurrent Fever." Drs. Starr, Kinnicutt and Musser took part in the discussion.

(To be continued.)

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

### Glutol in Preventing Pitting of Smallpox.

John Moir, in an extract occurring in London *Lancet*, states that glutol is a whitish powder, prepared by exposing sheets of gelatin to the vapor of formalin. The solvent action of glutol is facilitated by the addition of lard and by application the gelatin is dissolved and formalin liberated. He recommends it in suppurative conditions of the mouth, gums and tongue; carcinoma; tuberculosis; severe burns and chronic ulcers. But he especially recommends it mixed as follows as a preventive of severe pitting and deep scars from smallpox:

|                       |        |       |
|-----------------------|--------|-------|
| R. Glutol .....       | ℥ss-℥i | 15-30 |
| Paraffin (soft) ..... | ℥iv    | 120   |

M. Sig.: To be applied locally.

The same proportion has been employed in carcinomatous and epitheliomatous cases as well as in severe burns. It is entirely harmless as an application in diseases of the mouth, even when swallowed in considerable quantities. It has been employed by others with marked success in the treatment of warts, chancreoid growths and in syccosis vulgaris, although it took more time than most remedies; but it was easily handled, did not cause pain and left no scar.

### Removal of Dandruff.

The following outline of treatment is recommended by *Med. World* to be employed in removing dandruff:

|                      |       |    |
|----------------------|-------|----|
| R. Thymol .....      | gr. i | 06 |
| Olei lavendulæ ..... | m. v  | 30 |
| Pétrolati .....      | ℥ii   | 60 |

M. Sig.: Rub a small amount in the palm of the hand and apply to the scalp, first washing the head thoroughly with medicated soap. This should be done once or twice a week, followed by a wash containing resorcin and salicylic acid.

Hyde recommends the following as a lotion:

|                              |        |     |
|------------------------------|--------|-----|
| R. Hydrarg. bichloridi ..... | gr. ii | 15  |
| Ol. amygdalæ dulc. ....      | ℥ii    | 8   |
| Tinet. cantharidis .....     | ℥ii    | 8   |
| Spts. vini rect. ....        | ℥ii    | 60  |
| Aq. destil. q. s. ad. ....   | ℥vi    | 180 |

M. Sig.: To be rubbed into the scalp; or:

|                   |     |     |
|-------------------|-----|-----|
| R. Resorcin ..... | ℥ss | 15  |
| Alcoholis .....   | ℥ii | 60  |
| Aq. rosæ .....    | ℥vi | 180 |

M. Sig.: Apply locally to the scalp with friction.

As an ointment the following containing sulphur is recommended in treatment of all disorders of the sebaceous glands:

|                      |              |     |
|----------------------|--------------|-----|
| R. Sulphuris .....   | gr. xv to lx | 1-4 |
| Ung. aquæ rosæ ..... | ℥i           | 30  |

M. Ft. unguentum. Sig.: Apply locally.

The following is recommended by Veiel as quoted by Hyde:

|                          |                |       |
|--------------------------|----------------|-------|
| R. Ext. cinchon. ....    | gr. xx         | 130   |
| Bals. Peruv. ....        | gtts. xv       | 1     |
| Tinet. cantharidis ..... | gtts. xxiv-℥ss | 1.5-2 |
| Succ. citri .....        | m. xv          | 1     |
| Ung. pomat. ....         | ℥iiss          | 45    |

M. Sig.: To be rubbed into the scalp once or twice daily.

### Exophthalmic Goiter.

S. Tschirjeff of Kieff attributes this disease to the accumulation of waste products of albumin owing to the insufficiency of the thyroid gland. These waste products affect the cells of the medulla, especially those which regulate the action of the heart. He has succeeded in curing all recent cases and permanently benefiting the old-established ones by treatment designed to restore the thyroid gland to normal and regulate the heart's action. He paints the goiter with iodine every evening or every second evening. Then he applies a cold water bandage during the night and Faradizes the gland every second day. He also administers internally gr. iv to gr. viii (25 eg.

to 50 eg.) a day of a mixture of potassium iodid one part and sodium iodid three parts. The tachycardia is combated by convallaria. The patient is also instructed to take a warm bath every evening or every second evening. These baths, he states, prove very useful in soothing the patients and regulating the heart's action. All stimulants and violent exertion are forbidden. Two to seven drops of Fowler's solution are ordered if indicated. The improvement in six weeks of this treatment is very remarkable. Pregnancy is no contra-indication.

### Normal Salt Solution.

Himmelsbach, in *N. W. Lancet*, recommends, as a matter of great importance, relatively small and repeated injections of the normal salt solution subcutaneously. The quantities formerly given in this manner, from one to three pints, are entirely unnecessary, and according to his statement an equally specific effect can be produced upon the renal organs when the solution is given in smaller amounts, as shown by the elimination which is many times greater than the quantity injected. This has the advantage in that the time taken to do the operation is curtailed, which is of great importance in children. Lenhartz advocates injections subcutaneously of two to six ounces every three or four hours, and states that they have a better diuretic effect and cause less strain on the kidneys than a pint given several times a day.

### Incontinence of Urine.

The following has been recommended in treatment of incontinence of urine occurring in children:

|                     |     |    |
|---------------------|-----|----|
| R. Antipyrini ..... | ℥ii | 8  |
| Aquæ .....          | ℥i  | 30 |
| Alcoholis .....     | ℥i  | 30 |

M. Sig.: One teaspoonful at bedtime in a small amount of water.

### For the Relief of Flatulency.

|                        |      |    |
|------------------------|------|----|
| R. Creosoti .....      | m. x | 60 |
| Bismuthi subcarb. .... | ℥ii  | 8  |
| Glycerini .....        | ℥i   | 30 |
| Aq. menth. pip. ....   | ℥i   | 30 |

M. Sig.: One teaspoonful every three or four hours; or:

|                          |       |    |
|--------------------------|-------|----|
| R. Saccharin .....       | gr. i | 06 |
| Pulv. carbo. ligni ..... | ℥ii   | 8  |
| Bismuthi subnit. ....    | ℥ii   | 8  |

M. Ft. chartulæ No. xii. Sig.: One powder to be taken one half hour before each meal.

### Folliculitis Barbae (Barber's Itch).

The following is recommended by Merck's *Archives* in the treatment of barber's itch:

|                        |         |    |
|------------------------|---------|----|
| R. Acidi tannici ..... | gr. xlv | 3  |
| Sulphuris precip. .... | ℥iiss   | 6  |
| Zinci oxidi .....      | ℥iv     | 15 |
| Amyli .....            | ℥iv     | 15 |
| Pétrolati .....        | ℥i      | 30 |

M. Sig.: To be used morning and night.

Van Harlingen advised for acute cases a wash composed as follows:

|                                |       |     |
|--------------------------------|-------|-----|
| R. Zinci carb. (precip.) ..... |       |     |
| Zinci oxidi, āā .....          | ℥i    | 4   |
| Glycerini .....                |       |     |
| Liq. plumbi subacet., āā ..... | ℥ii   | 8   |
| Aquæ rosæ .....                | ℥viii | 240 |

M. Sig.: Use as a wash morning and night.

### Follicular Conjunctivitis.

J. W. Bullard, as noted in *Pediatrics*, states that mild cases may be cured by rubbing the everted lids with copper sulphate or alum and washing the excess off with sterile water. This may be done two or three times a week, and in the interval the following may be instilled three times a day:

|                      |          |       |
|----------------------|----------|-------|
| R. Zinci sulph. .... | gr. i-ii | 06-12 |
| Aquæ destil. ....    | ℥i       | 30    |

M. Sig.: Instill into the eye three times a day.

He states, however, that operative procedure is more rapid and very effective. With the usual aseptic precautions, and having applied cocain, pass one blade of Knapp's roller forceps, or Gifford's forceps, well back into the conjunctival cul-de-sac,

and the other over the everted conjunctiva, and with firm pressure pull from the eye. This breaks down and squeezes out the follicles. After this procedure mop the lids with a bichlorid solution (1-500), washing off the excess with a borie acid solution or sterile water. Repeat every one or two days, using the zinc sulphate solution from one to three times a day.

#### Corrosive Sublimate in Pertussis.

C. Calabro, according to the *Med. News*, treated 56 cases by painting the throat with the following solution:

|   |     |
|---|-----|
| R. Hydrarg. chloridi corros. .... gr. iii | 20  |
| Sodii chloridi ..... gr. i                | 06  |
| Aque destil. .... O i                     | 500 |

M. Sig.: Paint well over the pharynx, epiglottis and tonsils with a soft long-handled brush three times a day.

The author advises that the patient be fed before painting to prevent irritation of the empty stomach by the small quantity of the solution which is swallowed during its application. Of the 56 cases he states that 39 were cured with one daily application and 17 of the cases received three treatments daily in addition to other remedies commonly used in pertussis.

### Medicolegal.

#### Authorized Means to Prevent Spread of Diphtheria.—

The Supreme Court of Arizona says, in the case of Haupt vs. Maricopa County, that, in addition to the enforcement of suitable police and sanitary regulations, the boards of supervisors are empowered "to adopt such provisions for the preservation of the health of their respective counties as they may deem necessary, and to provide for the expenses thereof." The language used in the statute indicates a broad grant of power, and that it was intended to intrust to the board a large discretion concerning the means to be employed for the preservation of the public health. It would not be the part of wisdom to unduly hamper with restrictions the exercise of so important a function. The prevalence of contagion may require the adoption of different measures, according to the peculiar exigencies of the situation which is presented, and the court goes on to say it does not feel justified in prescribing a limitation which might, in effect, tie the hands of the board when the urgency was the greatest. The question in this case was not whether liability for certain property destroyed under the advice of a physician to prevent the spread of diphtheria could have been avoided by the adoption of a different course of action, but, rather, one as to whether, under the law and the procedure taken, an obligation had been created against the county. The property destroyed consisted of the house occupied by the sick family, admittedly a "small affair," and its contents of furniture, household effects, stores, and personality. Considering the circumstances, the court is of the opinion that the board of supervisors possessed the requisite power, under the foregoing grant, to contract with the owner to pay him for the taking and destruction of his property, as the most efficient means for the eradication of the disease with which it was infected. The question of the sufficiency of the evidence to establish such contract was one which should have been left to the jury.

**Constitutionality of Medical Practice Act.**—The Supreme Court of Kansas holds, in the case of State vs. Wilcox, that chapter 254 of the Laws of Kansas of 1901, "An act to create a state board of medical registration and examination and to regulate the practice of medicine, surgery and osteopathy in the state of Kansas, prescribing penalties for the violation thereof, and repealing chapter 68 of the Session Laws of 1870," is a constitutional enactment. It says that if the title had been "An act to regulate the practice of medicine and surgery," instead of the more elaborate one used, it would have covered every provision of the statute, and under numerous decisions would have been considered as a single subject, and not void because of its generality. The provisions fixing the standard and testing the qualifications of medical practitioners are not prohibitive in their nature. It is not an arbitrary discrimination, nor an invalid deprivation of right, to provide

that only those possessing a knowledge of the human system, of its ailments and diseases, and who possess the skill to apply remedies and practice the art of healing, shall be allowed to practice. If such regulations and conditions are adopted in good faith, and operate equally upon all who may desire to practice, and who possess the required qualifications, the fact that the tests and conditions imposed by the legislature may be rigorous will not invalidate the legislation. It is to be presumed that the board of examination and registration, like all other tribunals vested with such powers, will act with judgment and conscience, and will deal justly with all applicants for license. It is vested with discretion to determine the standing of medical schools from which the diploma comes, and also whether a physician who submits to an examination possesses the requisite character, learning and skill; but it is not an arbitrary, capricious and unrestrained discretion. The law requires that the board shall exercise an honest and impartial judgment and discretion in accordance with just rules, and if the board should depart from this course, and should act arbitrarily and unjustly towards applicants for license, the courts are open to them, and will award them relief and protection. The act is not invalid because it provides that "nothing in this act shall be construed as interfering with any religious beliefs in the treatment of diseases, providing that quarantine regulations relating to contagious diseases are not infringed upon." The express exclusion of the element of religious belief in the application of the law was hardly necessary. Religious freedom is guaranteed by the constitution, and without mention in the statute would have been implied. And the court can see nothing in this provision which makes an illegal discrimination against or in favor of any class of physicians. Neither, it says, is there any force in the objection to the provision making the statute inapplicable to the administration of domestic medicines, or to gratuitous services which one friend or neighbor may render to another. It is the practice of medicine and surgery for compensation that is sought to be regulated and controlled, and not the use of home remedies, nor the neighborly offices which one may kindly and gratuitously perform for another.

#### Anticipating Injury from Malpractice—Curettement—Experimenting.

—The Supreme Court of Wisconsin says, in the malpractice case of Allen vs. Voje, that the rule is without exception that liability in damages for acts or conduct lacking in ordinary care can not arise unless the act be such that an ordinarily careful person would anticipate that some injury to another might probably result therefrom. Indeed, that circumstance is an essential element of actionable negligence. With mere carelessness the law has no concern, unless it be such that some injury may be reasonably anticipated. But it is not essential to the existence of actionable negligence, or of liability therefor, that a reasonably prudent person would have foreseen the exact injury which did result. It suffices that some injury might reasonably have been foreseen to occur. And the court says that it is convinced that there is no room for difference of opinion as to whether, from the lack of skill, care, and precautions ordinarily exercised by physicians in treating or operating upon the highly sensitive portions of the feminine anatomy involved in the treatment in this case, where a curettement was performed, an injury must be anticipated as likely to occur. To hold otherwise would involve a contradiction in ideas. It is the very peril of physical injury which necessitates a code of precautions in diagnosis and treatment by physicians and surgeons. They serve no other purpose. Taking for illustration the precautions to render an operation aseptic, it is apparent that they are adopted for no other reason than that every physician anticipates injury to the patient as probable in their absence. It is unreasonable to say that a physician may improperly and negligently exonerate the lining of a delicate internal organ, and escape liability by doubt as to whether he, in the exercise of reasonable care, should have anticipated injury to the patient thereby. The relationship between such an act of the physician and the physical condition of the patient is so intimate that he must necessarily anticipate some physical effect as the result of such operation and, of course, that such effect will

be bad if his act be improper or improperly done. The view above expressed, the court says, is confirmed by the fact that in no decided case cited by counsel or found by the court, nor in any text-book, is declared the necessity of any finding of this element of anticipation of injury from professional negligence in medical treatment or surgical operations. Unformly, liability is made to depend on whether injury in fact resulted from departure from recognized methods or omission of usual precautions. In line with this, the court says that it has little doubt that, if the first case of vaccination had proved disastrous and injured the patient, the physician should have been held liable. It does not believe that a physician of standing and loyalty to his patients will subject them to mere experiment, the safety or virtue of which has not been established by experience of the profession, save possibly when the patient is in extremis, and fatal results substantially certain unless the experiment may succeed. It also suggests that it is not impossible that cases of malpractice might be presented wherein the proximate causation of injury should be passed on by the jury, although it does not consider that it was necessary here.

## Current Medical Literature.

1. **Dietetic Aphorisms for Infant Life.**—The following are the aphorisms offered: 1. Nature's way and Nature's food are the best. The possibility of improvement of the quality or quantity of mother's milk should always be considered before putting the child on artificial feeding. 2. We should do the best we can with what we have. Here Gridlith protests against the adoption of any one fixed formula for infant feeding. The mixture must be made to meet the special requirements of the child. 3. Keep up with the times. What is unscientific will not pass muster. He gives formulas and equations of infant food, giving the most recent and from experience the most suitable. 4. Know what you want. We should know why we give this or that mixture to certain children and should not be lazy or too adherent to old ways. 5. Go slow and do not increase the strength of the milk too rapidly or introduce too much starchy food. The age of the child should not be the guide, but its general condition, especially its weight, should be. 7. Lastly, he mentions the starvation treatment, meaning by this the judicious temporary reduction in the amount and strength of the food given, to meet the necessities of the case.

2. **Gelatin.**—The following are the conclusions of Wood's paper: "1. Pepsin digestion of gelatin does not destroy its coagulating effect on the blood. 2. The resulting product is dialyzable, and therefore capable of absorption. 3. The administra-

tion of gelatin by the mouth in the treatment of hemorrhage is, therefore, a rational procedure. 4. Gelatose seems to antagonize, if given in sufficient quantity, the anticoagulating action of peptone."

**3. Milk Percentage.**—The method here given by Freeman is summarized as follows: "This method of obtaining percentages in modifying milk is simple and is applied as follows: 1. After having decided on the number of feedings for the 24 hours, the amount to be given at each feeding, and the formula of the food required, first determine the desired relation between the amount of fats and proteids, and obtain a cream or milk in which these constituents exist in that proportion. 2. Dilute this cream or milk with the required amount of water. 3. Determine the percentage of sugar required for 24 hours' feeding and order the same in packages containing the required amount. 4. If lime water is added, the amount so added must be deducted from the amount of water used."

**5. Mastoid Operation.**—Dean insists on the greater danger of non-operative over operative treatment, and points out the symptoms to which attention should be given, namely, examination of the fundus to see if there is a choked disc, the result of an increased intracranial pressure. 2. Examination of the tympanic membrane for perforation and discharge, which is the most frequent cause of mastoiditis. 3. Partial or complete obstruction of the drum with pus in the middle ear. 4. Necrosis in the attic or posterior wall of the middle ear. 5. Cholesteatomatous masses in the middle ear. 6. Sudden elevation of temperature to 103 to 105. No one of these symptoms will make certain the diagnosis but will suggest it. He insists on the danger of neglect.

**9. Joint Tuberculosis.**—Phelps describes orthopedic apparatus, with illustrations for tuberculous joint disease and reiterates his former expressed opinion of the need of early operation in any joint trouble associated with abscess. He is convinced that a single rheumatic joint never occurs. If rheumatism exists, more than one joint is affected; any single joint disease is either purulent, tuberculous, gonorrheal, or is due to pneumococcus or some central nerve lesion. If one joint becomes affected after another it is presumptive evidence of secondary infection.

**10. Deafness.**—Bates describes an operation which he has employed in cases of chronic catarrhal middle-ear deafness where there was overgrowth of the connective tissue in the form of adhesions, the fibrous growth continuing on the membrane and the functional defect due generally to this connective tissue growth. All the patients improved by this treatment had symptoms of an obstruction to the sound-conducting part of the ear. All heard the Hartmann tuning forks better by bone conduction than by air. Timitus was not always present. The treatment was only employed after other well-known methods had failed. "The object of the operation was to obtain room for treating the region of the oval window, and not to improve the hearing immediately. The patient received no special preparation. The hair in the neighborhood of the ear was not cut or the parts treated with antiseptics, as is the practice of many operators previous to a mastoid operation. An incision was made through the skin over the mastoid, close to the insertion of the auricle and the bone, beginning above close to the hair and ending below at the tip of the mastoid. The auricle was rapidly dissected from the bone with blunt scissors until the external auditory canal in its cartilaginous portion was cut through. With a chisel the superior and posterior walls of the external auditory canal were removed until the antrum was reached. A bent probe was inserted in the aditus ad antrum and was found a useful guide in preventing injury to the facial nerve in the further steps of the operation. The outer wall of the attic, the membrana and ossicles, and overhanging bone were removed, converting the tympanum, the external auditory canal, and the mastoid antrum into one cavity with smooth walls. During the operation the hemorrhage was controlled in the usual way, either by pressure with moist pads of cotton, by hot water, or by the use of artery forceps. After the completion of the operation, the cavity was dusted

lightly with iodoform powder. The skin wound was closed with sutures (silk No. 000) and covered with a collodion, iodoform and cotton dressing. A small pledget of cotton was placed in the orifice of the external auditory canal, the ear covered with a large wad of cotton, and a bandage applied. The day after the operation the bandage was removed and was not used again. Secondary hemorrhage occurred, but was not alarming. The sutures were removed with the collodion dressing usually in five days. Primary union of the skin wound was the rule, with healing of the parts without deformity. The patients were confined to bed until recovery from the anesthetic. The ear did not in any of my cases produce uncomfortable symptoms. Most of the patients were able to go outdoors the day after the operation. To prevent infection of the middle ear, the patient instilled twice daily in the external auditory canal a solution of bichlorid of mercury, 1 to 3000." This was continued during the after-treatment, which was for the removal and prevention of recurrence of connective tissue from the inner wall of the tympanum and was not altogether easy. He found the cutting operation better than caustics for this purpose, using local anesthesia. The reaction from the use of the knife caused a temporary loss of hearing which later returned. The removal of the connective tissue is soon replaced by soft material which becomes hard and fibrous. He thinks it best to remove this as rapidly as it forms, therefore he removes small portions at frequent intervals. The patient can continue the treatment at home by instillation of peroxid of hydrogen, bichlorid of mercury, or other antiseptic solution followed by olive oil. Some antiseptic solution was found necessary to be used daily to prevent infection. When the cases are cured the inner wall of the tympanum is lined with a thin, light-colored, smooth, dry membrane. Most of the cases were also benefited by treatment prescribed by the family physician and in some cases treatment of the nasopharynx is also of value. The average time to restore hearing for ordinary conversation at ten feet was about six months. A number of cases are reported. He says: "The treatment was found beneficial in a class of cases which were not benefited by treatment of the nasopharynx or Eustachian tube or by operative measures in the middle ear. Perhaps the only objection to this new method is the necessary time required in order to obtain good hearing. Yet I believe this objection can be overcome after further experience has perfected the technic of removing the excess of connective tissue from the inner wall of the tympanum."

**14. Surgery of the Heart.**—Nietert draws the following conclusions from his observations and studies on the suturing of heart wounds: "1. Gentle manipulation may be applied without producing shock. 2. The introduction of the suture produces but a slight irregularity in the heart's action. 3. Heart wounds heal rapidly. 4. Intrapericardial pressure is increased even if hemorrhage occurs during diastole alone. 5. All heart wounds, in which there is danger of fatal hemorrhage, should be sutured. 6. If the wound does not involve the pleura, the extrapleural route should be employed, as described above. 7. If the pleura has been injured, the intrapleural method should always be employed, and the flap devised by Rotter is the best. 8. Although it is advisable for the surgeon to familiarize himself with the methods of operation and the flaps devised by the different operators, a thorough knowledge of the anatomy of the region is most essential and each operator should modify the flaps as best suits his case.

**15. Uric Acid Diathesis.**—Edsall criticises the theories of uric acid and its connection with gout, maintaining that the methods have been false, though those who have been recently stating that uric acid is absolutely nontoxic have not sufficient ground for their assertions and are opposed to convincing testimony. He is inclined to believe that uric acid does not cause any notable evidence of intoxication and does not produce the general symptoms of gout, though it may produce much of the local difficulty at the time of the attack as well as in the interval. There is little ground for the belief that it has a purely mechanical action. He suggests that it is possible that the uric acid in gout is different from the uric acid in other

conditions. The relation between uric acid and the so-called uric acid diathesis is a complex condition and he says a large class of disorders have been called by one name, which, so far as we know, is not actually deserved by many of them. We do not know the true cause. He also considers the theory of the xanthin bases in excess being the cause of gouty manifestations, as also the result of faulty methods of study.

**16. Static Electricity in the Insane.**—Chase finds that the neurasthenic forms of mental ailment, such as melancholia, are decidedly benefited by the static breeze and spark directed to the spine or to various parts of the viscera. He reports cases which seem to have been benefited in this way. The remedy not only does good by its direct effects, but also through suggestion.

**17. Solanum Carolinense.**—This plant, which belongs to the *Solanaceæ* family and is known under the names of horse-nettle, bull-nettle, etc., has been used for a number of years by negroes in the South in the treatment of epilepsy with excellent results. Thrush has investigated the substance and tried it in four Philadelphia hospitals in 25 cases of epilepsy with encouraging results. He offers the following conclusions, which he thinks are warranted: "1. It is of great value (probably better than any one known remedy) in grand mal of idiopathic type without hereditary taint and where the disease has begun beyond the age of childhood. 2. It is perhaps next of greatest value in hystero-epilepsy with marked convulsive seizures. In cases of petit mal the drug does not seem to do the great good that we have noted in the major type of the disease. 3. In cases of well advanced epilepsy of any type in which there is degeneration of the cerebral neuron, the drug will act specifically for a time even better than the bromids, but it will finally be determined that the bromid salts will ultimately control the attacks better in these cases. 4. The foregoing clinical study has brought out sufficient clinical evidence to warrant the statement that the inherent advantage of vegetable depressomotors is great as compared with any mineral salt given with the same intent, since destruction of the blood corpuscles by the latter is a most detrimental feature towards lessening the resistance of the individual in a disease, where, above all, the constitutional tonicity should be favored as ideal treatment. 5. A thorough impregnation of the nerve cells can alone be had and therefore cure hoped for in epilepsy in proportion as solanum is pushed to the fullest physiologic dosage and maintained through periods of months, a year not being too short a time to warrant its discontinuance. 6. The fluid extract of the drug made freshly is the ideal form of pharmaceutical preparation given in ascending doses commencing with one fluid drachm and increasing to the full constitutional effect. 7. It is to be decidedly preferred to the bromids in those cases in which it can be used advantageously, because no toxic symptoms follow its free administration and the mental faculties are not impaired by its use."

**20. Surgery of the Stomach.**—The first problem of gastric surgery noticed by Mayo is the difficulty of making a diagnosis, every operation being to a certain extent exploratory in its incipency. The only cases of cancer of the stomach which he has been able to diagnose sufficiently early to extirpate are those where obstruction and dilatation were present. There is a large group of chronic dilatations where there is no apparent adequate cause, and he queries the assumption of pyloric spasm. In very few cases did he find a definite thickening in the pyloric ring; in these there was very little dilatation. In a number of cases angulation was present, that is, a high-lying pylorus somewhat firmly fixed with a sharp bend of the stomach downward and immediately proximal to it. He has seen a number of such and these may be due to adhesions resulting from perigastritis or gastric ulcer of cholecystitis. The most perplexing cases, however, are those of neurotic origin, in which he places the various grades of gastroparesis. In the purely neurotic variety, the symptoms of ulcer may be so perfectly simulated as to lead to an exploration which proves negative. The stomach may contract until it is no larger than the colon, and the pylorus dilate so as to admit two or more fingers. The question when dilatation with retardation of the passage of

food out of the stomach demands operation, largely, he says, depends on the experience of the surgeon and the disability of the patient. He describes the methods of making gastric drainage, the value of which is apparent and needs no argument. Various operations on the stomach are mentioned and he finds gastro-enterostomy the most satisfactory one. He has performed it 80 times with 8 deaths, and details his analysis of the cases and gives the methods. It affords drainage, which is one of the essential conditions and prevents stagnation and vomiting of food and relieves the patient. He uses the Murphy button in the operation and says that the main thing is that the operation should be low down, near the greater curvature in either operation, either posterior or anterior; it is bad practice, he thinks, to make it about half way between the lesser and greater curvatures because there are but few blood vessels in the locality. It leaves a pouch into which the bile and pancreatic secretions can easily enter, and it encourages "vicious circle."

**21. Thrombosis of the Cavernous Sinus.**—Several cases are reported by Dwight and Germain, who discuss the condition and the possible effects of operation. In one case with cavernous thrombosis, operation was followed by apparent relief of symptoms, but the patient soon died. An incision into the one sinus instantly and completely relieved the interference with circulation in both. So far as they know, the operation has been done but once before, by Hartley and Knapp; the patient in this case survived for a considerable period and finally succumbed from the original disease, sarcoma. They think, however, that the two operations performed show that thrombosis of the cavernous sinus is distinctly an operable condition, and there is some hope for the decreasing of the mortality by active interference.

**22. Tuberculosis.**—Otis' article sums up his arguments in the following: "1. Consumption is one of the most prevalent diseases, especially among the poor. 2. It attacks its victims at the most useful period of their lives. 3. It is contagious or communicable and hence avoidable. 4. It is very curable, especially so when taken at its inception. 5. It is most prevalent in crowded portions of a city and in tenement-house existence. 6. The contagion is restricted, as with other contagious diseases, by isolation. 7. The dried sputum is the principal source of contagion. 8. Sanatorium treatment, especially for the poor, gives the best results with favorable cases. 9. Sanatoria and consumptives' hospitals afford the best means of isolation. 10. By means of such institutions, we steadily and surely reduce the existing number of cases. 11. Every means which increases the resisting power of the individual decreases his chances of contracting the disease. 12. This resisting power is established and maintained by favorable environment, as to abode, place of labor, rest, food, etc. 13. Economically, it is probably less expensive to care for the poor consumptive in a sanatorium or consumptives' hospital than in any other way. 14. Morally, we owe the destitute consumptive in our midst a reasonable opportunity for recovery or a decent place to die in. Sanatoria and consumptives' hospitals are in the air. The people are awakening to their importance." Sanatoria and consumptives' hospitals are, he says, the order of the day, and the movement will go on until every city has made provision for the poor consumptive.

**23. Cholelithiasis.**—Berg states his conclusions as follows: "a. Indications for medical treatment: Cholecystitis pain or attacks of biliary colic, in either case unattended with fever. b. Indications for Surgical Treatment: 1. Operations of choice—undertaken in the quiescent period, with the object of avoiding serious complications, a simple procedure, and followed by 2 to 3 per cent. mortality. (a) Severe cholecystitis pain, or oft-repeated uncomplicated attacks of biliary colic, persisting in spite of medical treatment. In virtue of which symptoms the patient becomes invalided, and incapacitated for work. (b) After the first attack of acute cholecystitis, associated with fever. 2. Compulsory operations—undertaken at any time of the day or night; often amidst unfavorable surroundings, and in patients who are septic, emaciated, and of low vitality. Difficult and laborious procedures, and attended with high

mortality—50 to 75 per cent. (a) Foudroyant and intensely acute attacks of cholecystitis. (This may be the first indication of calculous disease, but usually follows previous milder attacks.) (b) Hydrops, empyema, gangrene, or perforation of the gall-bladder, cholemia, abscess of the liver, and diffuse peritonitis."

**26. Strabismus.**—Roosa insists on the non-existence of monolateral strabismus, except in cases of paralysis. All strabismus with the exception of paralytic squint is necessarily concomitant and he would adopt the names suggested by Panas of "functional" and "paralytic" strabismus to describe the two varieties. He now invariably, for non-paralytic or functional strabismus, divides both the interni in convergent strabismus, and both externi in divergent strabismus, having stretched them according to the rules laid down by Panas.

**27. Hydrophobia.**—Dulles replies to criticisms, saying that he has not denied that rabies is a specific disease or that the muzzling of dogs is not a preventive of hydrophobia, but still claims that the muzzling laws in England have been inefficient, and that he has not misrepresented Pasteur. His idea that hydrophobia can be conveyed by the bite of a non-rabid dog is still maintained. The article is decidedly controversial in tone.

**29.**—See title 45, below.

**30. Phthisiophobia.**—Knopf's article gives a history of the recent action of the New York Academy of Medicine protesting against the decision of excluding well-to-do consumptive immigrants by the Treasury Department. He points out that the effect of such teaching has been to create hardship to innocent sufferers, even those who are not infected with the tubercle germs. He also points out that the order of the Treasury Department was countermanded by President Roosevelt when the facts were laid before him.

**31. Saline Solution in Shock.**—The cases of shock that are not benefited by injection of saline solution have been studied experimentally by Crile, who gives the details of his researches. He finds that there is a well-marked and characteristic group in which saline solution is of but temporary aid and does not alter the general condition. Vasmotor breakdown is an impairment which can not be relieved by this means any more than by drugs. The benefits from saline solution in shock are in cases of hemorrhage alone or hemorrhage with shock, and result from restoring the fluid to a normal volume and adding force to the venous stream, but when the vasmotor mechanism has become exhausted it can not respond.

**32. Digitalis.**—The motif of Porter's article is to show that the prolonged use of digitalis acts damagingly on the heart muscle, both by its action as a muscle poison and by its interference with cardiac nutrition through the circulation. Digitalis, he thinks, is of service temporarily in certain cases by improving the mechanical action of the heart, as in mitral insufficiency and stenosis, but in aortic lesions there seems to be no good reason for using it in any stage. It is contra-indicated in fatty degeneration or in enfeebled condition of the heart muscle. In hypertrophy of the heart it might theoretically be useful in cutting down the nutritive supply, but is too dangerous for such service, and, as a rule, is of service for only a few days at a time at the longest. It should only be given to influence the heart and circulation when the arteries are very much relaxed, and pulmonary and systemic veins are overfilled with blood. In such cases it will tighten up the vessels and by augmenting the power of the systole will force a large volume of blood into the arterial system. This accomplished, it should at once be stopped and reliable remedies used. The use of nitroglycerin only partially relieves the damaging effects of digitalis and does not antidote this toxic action.

**33. Kidney Suppuration.**—Johnson discusses the conditions in pyelonephritis and pyonephrosis, solitary or local abscesses and cases of suppuration occurring as a secondary condition in hydronephrosis. Cases where tuberculosis or renal calculus is strictly the cause of the disease he does not consider. He finds in regard to pyelonephritis that in many cases it is limited to one kidney and early operation often leads to brilliant results.

In pyonephrosis the operation of simple nephrotomy leaves much to be desired, and, although in unfavorable conditions it may be all we desire to perform, this is not usually the case. All the openings and passages containing pus must be opened up; this involves traumatism nearly equal to that in nephrectomy. The kidney must also be pulled down and forward for inspection and the disturbance of its vessels impairs the nutrition of the organic kidney substance. He therefore rather favors primary nephrectomy in such cases and thinks that nephrotomy can hardly be regarded as the operation of choice, nor even secondary, though nephrectomy is not always practicable. It should be remembered that septic nephritis of considerable severity in one kidney is not always a contra-indication to the removal of its fellow, as is shown by the case of Israel, and also by another to which he here refers. Excision of the diseased portion in local abscess is brilliantly successful in some cases. In case of infected hydronephrosis timely conservative operation is often effectual. The patient can be relieved of septic irritation by incision and drainage and, if the kidney is still capable of functional activity, recovery may take place. A much larger portion of these cases are cured by conservative operation than in pyonephrosis, and nephrotomy is the operation of choice. When nephrectomy is required, the kidney has long ceased to functionate.

**34. Cystoscopy in the Female.**—Bierhoff describes in detail the technic of cystoscopy in the female and calls attention to the difficulties of satisfactory bladder examination, in spite of the fact that the introduction of the cystoscope is easy. He insists on thorough exploration of the cavity of the bladder previous to cystoscopy, using the unlighted cystoscope as a sound and calls particular attention to the danger of infection if cauterization occurs with the cystoscope. In case it has occurred it is advisable to wash out the bladder thoroughly and inject about 50 c.c. of a one-eighth per cent. solution of nitrate of silver, which should be allowed to remain until next urination.

**36. Smallpox.**—Certain difficulties in the diagnosis of smallpox are noticed by Hardaway, including the differentiation from some systemic disorders like cerebrospinal meningitis, the nervous form of influenza, which may resemble the prodromal stage, certain cases of menstrual eruptions, erythema, etc. The erythematous initial rashes of smallpox have nothing characteristic about them. The petechial or hemorrhagic rash of the cruro-abdominal triangle, sometimes seen extending to the side of the body, is very rare, but always means smallpox. In the papular stage it is sometimes possible to confuse smallpox with measles, but the differences in the character of the fever and catarrhal symptoms usually clear up the case. In the rare papular or button-like measles there may be trouble. An examination of the mouth and pharynx will be of value here, because in cases of smallpox the lesions will have vesiculated while yet papular on the skin. The history may give trouble in some cases of varicella. Hardaway has seen several cases the past winter of what may be called erythema papulatum. In one patient in particular there was fever, pain in the legs, headache, gastric disturbances and various discrete eruptions of hard, small, red papules of the face, arms and legs. In another case there was some eruption of the papules which on the second day showed slight vesiculation and, if one was not intimately acquainted with smallpox lesions and the manifold peculiarities of cutaneous diseases in general, mistakes in the diagnosis might occur. He mentions here also a certain type of pustular syphilid and iodic papules which may closely simulate the papules of smallpox.

**45.**—See title 29, above.

**55.**—See title 178, below.

**56. Appendicitis.**—Hillsman discusses the medical and surgical treatment of appendicitis and concludes that it is better to operate prematurely than to delay too long and that we cannot anticipate the severer forms and have no method of telling the catarrhal cases from the gangrenous ones, hence the safety of the general rule of operation. Acknowledging the recovery of 40 to 60 per cent. under medical treatment alone, this is not

equivalent to a mortality of less than 1 per cent. from early and timely operation and does not affect the rule.

**58. Liver Secretions in Therapeutics.**—Whitney suggests the possible use of the bile salts as a solvent for biliary calculi and for stimulation of the biliary secretion, also apparently stimulating the glycogenic function of the liver. He has seen cases of diabetes and ordinary glycosuria much benefited and a few cleared up entirely by this treatment. The question of the use of some of the other ferments of the liver is one that has never been clinically worked up, but the possibilities of the use of the oxidizing ferment isolated by Jacobi are obvious and one of the reasons why experiments along this line have not been done is, perhaps, the difficulty in our determining definitely the lesion of the liver.

**63. Hodgkin's Disease.**—The case reported by Dodson failed to show any tubercular infection either by microscopic examination of the gland or the tuberculin test. He doubts the propriety of attributing all cases of this condition to tuberculosis. It is probably of infectious origin, but the infection is not yet known.

**65. Heredity.**—Reid's article is largely an exposition of the Weissmann theory. He appears to believe that this theory is held by all the most advanced authorities and is revolutionary in its effects on our ideas. He does not seem to be aware of the large class of Neo-Lamarckian biologists who reject it more or less totally.

71.—*Ibid.*, p. 997.

72.—*Ibid.*, p. 1058.

73.—*Ibid.*

79.—This article has appeared in *THE JOURNAL* of April 12, p. 911.

**81. Goiter.**—Cuthbertson reviews the whole subject and calls attention to the value of hydrastis as a special treatment in the goiter of puberty and pregnancy. He has administered it in doses of one-half a grain of the dry extract three times daily after eating, and in twenty-five unselected cases he effected a cure by this method.

**82. Anesthesia.**—Eisendrath gives a comparative table of the physiologic action of ether and chloroform and their indications and contra-indications in practice. Ether should not be given when there is an increased arterial tension, as in atheromatous conditions, nor when great tympanites or other conditions exist which will interfere with the action of the diaphragm. Nephritis is also a contra-indication. Chloroform should never be given when it is necessary to administer it for over an hour, on account of its poisonous action on the heart. It should not be given in decreased arterial tension and blood pressure, as, for instance, when there has been a dangerous loss of blood, and in other cachectic or anemic conditions. The so-called thymic state is seen from recent researches to be another contra-indication. The danger point is much less evident in chloroform, and, therefore, constant watching of the pulse and respiration is required. Lowering of the head is useful to prevent a tendency to syncope. Another point is to administer chloroform drop by drop, never giving large quantities at a time, and with a free dilution of air. The patient should be kept on his side as much as possible during the administration of the chloroform and the anesthetizer instructed in the best method of pulling the jaw forward. Ether causes increased secretion of the mouth and inspiration of this secretion has sometimes caused pneumonia, but keeping the head dependent, lowering the trunk and turning the head to one side will help to prevent the mischief. There is little danger in using ether, other than from bronchial irritation, if these suggestions are followed. The idea that acute pulmonary complications are more frequent after ether seems to be incorrect. He sums up as follows: "1. Limit as much as possible the administration of a general anesthetic, using the method of Schleich as much as possible. 2. Chloroform should not be given in myocarditis. In other cardiac conditions it is not as dangerous as was formerly thought. 3. Ether should not be

given when there is any hyperemia or stenosis of the respiratory tract. 4. Chloroform should not be given in the status thymicus. 5. Ether is in general contra-indicated in diseases of the kidney. 6. Chloroform causes fatty degeneration of the heart muscle, liver and kidney, in prolonged administration. 7. In chloroform the anesthetizer should watch the pupils, pulse and respiration constantly. 8. We can avoid chloroform syncope by keeping the head low and turned on one side, and avoid the pulmonary complications of both ether and chloroform by keeping the head below the level of the body to allow the mouth secretions to run out, by preventing the chilling of the patient and avoiding conditions which favor hypostasis and interfere with action of diaphragm. 9. The order of procedure in case of syncope should be understood by all who are responsible for patient, viz., raise foot of table, artificial respiration, massage of heart, rhythmic tractions of tongue and intravenous transfusion. If these are of no avail, use the method of Prus, exposing heart and making direct mechanical stimulation, or intratracheal insufflations. Hypodermics are of little avail until the heart beats."

**89. Oral Pathology.**—Rhein calls attention to the importance of paying attention to the condition of the mouth as affecting the general conditions of the body, especially as an etiologic factor in auto-intoxication.

**90. Waiver of Privilege.**—Peltz, who is a lawyer, thinks that the amendments to the New York law prohibiting the waiver of privilege on the part of the patient, except when done in open court, should be immediately rescinded and that the waiver should be made at any time and at any place. The effects of the amendments are to nullify the waiver given in life insurance contracts, and while it is right for companies to issue incontestable policies it is not right for the law to compel both parties to make their contracts incontestable, which is the result produced by the amendments.

**91. Utility of Convulsions; Their Occasional Value.**—Spratling calls attention to the importance of occasional epileptic fits as a danger signal in certain cases. It may be sufficient warning to put the patient on his guard and prevent his becoming a confirmed epileptic. Another way that an occasional fit may be of benefit is in giving vent to the nervous strain and apparently neutralizing or destroying the autotoxic poisoning which causes it. He refers to cases illustrating both these facts.

**96. Some Unusual Drug Effects.**—Dunning remarks upon the occasional bad effects of iodid of potassium in increasing the neurotic conditions of lead poisoning and reports a case which was lost, he thinks, in this way. He also reports a case of mental disturbance produced by digitalis, which was relieved when the drug was discontinued. Arsenic he also mentions as producing motor symptoms prior to the sensory, and he reports a case which was significant from the absence of the usual toxic effects, thus accounting for the too prolonged use of it in this instance.

**97. Rectal Stricture in Women.**—Rothrock reports three cases of rectal stricture in females due to inflammatory conditions in the pelvis, in one so serious as to require colotomy for its relief and in the others giving rise to serious inconvenience. He thinks the reason why stricture does not more frequently occur is that pressure alone from the size of the tumor seldom causes obstruction and there must be considerable peri-rectal infiltration before the mischief can be produced. It is not at all uncommon in local inflammatory conditions in the abdomen to see the intestines firmly adherent in a mass of exudate and yet have the bowels move naturally.

**112. Tinnitus Aurium.**—Harris reviews the symptoms, treatment, etc., of tinnitus aurium and finds it a very common and annoying symptom in ear disease of not always very well understood origin, but due in many cases to the interference with the sound waves. It does not always mean deafness, and much can be done for it if the exact cause can be discovered. Drugs are disappointing; strychnin seems to be the best of them when local treatment has failed. A careful study and recording of cases is necessary for their proper management.

**113. Influenzal Otitis.**—Goldstein finds that: "1. Epidemic or endemic influenza is the etiologic factor in this affection. 2. A careful differentiation should be made between simple otitis media and influenzal otitis. 3. Free incision of the drum membrane at the earliest indication of effusion into the tympanic cavity should be made. This free drainage should constitute the most important principle in the treatment of this affection. 4. A guarded prognosis should be given, especially as concerns the complete restoration of hearing. 5. Conservatism is urged concerning operative interference when mastoid symptoms appear, as many of these symptoms are accompaniments of influenza and should be regarded as neuralgias rather than evidences of suppuration."

**114. Septal Deviations.**—From his observations, Jackson sums up as follows: The turbinated bodies in health and disease swell at night during sleep, the swelling being greatest in the inferior one and on the side next to the pillow. This periodic swelling, aided by the irritation of acute coryza and acute and chronic rhinitis, is often a primary and secondary factor in the production of septal deviation, both before and after operation, the deviation being usually of the cartilaginous septum, but often of the anterior bony portion as well. This etiologic factor is usually overlooked because it occurs in the night, disappearing prior to office examination. When the patient sleeps habitually one side the turbinal pressure is always in one direction. In other cases one turbinal being larger and more expansible than its fellow, the septum is pushed by it into the position of deflection which in time becomes permanent, while the larger turbinal becomes larger, which change is pathologic. The idea that it is a physiologic compensation and should not be touched, is the foundation of failure of attempts at correction of septal deviation. Almost every case of deviation demanding operation requires resection of the inferior turbinals on the concave side for two purposes: to secure immediate and permanent correction of the septal deviation and to secure adequate nasal respiration during sleep. It is an error to base the estimation of the adequacy of the nasal respiratory canal on either the patient's statement or the size on inspection of the canal, whether the parts be cocaineized or not. If the imprint of the inferior turbinal is seen on the septum, it is a certain indication for a radical resection of the inferior turbinated body, including a fringe of the bone on the concave side. Soft hypertrophies will expand at night and exert pressure and yet shrink so small as to leave a free and open channel during the day. These often do more harm than the hard hypertrophies and if left untouched or merely canterized with a galvano-cautery the cases might as well be left alone. If the resection of the turbinal be sufficiently radical there will be no need of a Mayer, Aesch, or Kyle tube, nor of packing to hold the septum in its position. He asks the skeptic not to act on theory, but to go home and take the case that failed of cure, cut out the inferior turbinal on the concave side, and after this is healed do his septum operation over again and note the result.

**118. Serum Therapy.**—The complications of diphtheria with streptococcus infection led von Quast to try to obtain a serum which would be effective against both types. Correspondence with Parke, Davis & Co. induced them to prepare for him a serum from a horse first immunized against tetanus, then streptococcus and then diphtheria infection. He has employed it on 8 cases, 3 of which were virulent and malignant types of scarlatina, with the best results and also reports a case of diphtheria with mixed infection, in which it was employed with favorable outcome. He hopes that further clinical trial of this serum will be made.

**123. Tuberculosis.**—Vaughan notices certain cases of tuberculosis and calls attention to the communicability of the disease and the importance of good feeding in the cure of incipient cases. He says he regards rest, proper feeding and the use of such tonics as strychnin the best and practically the only things needed in the early stages of pulmonary tuberculosis. He also uses nucleinic acid in the early stages, though there is nothing specific in its action and it is simply a tonic for the phagocytes of the body. There are some cases that are pos-

sibly aided in this way. It may, however, do harm in advanced cases. He has used it hypodermically and intravenously. He also remarks that in every case of loss of weight or of hemoptysis that symptoms should not be considered due to something else until one can be sure that it is not due to tuberculosis. In 91 cases out of 100, hemoptysis means pulmonary tuberculosis.

**134. Miners' Diseases.**—Coleman finds certain pathologic conditions frequent among miners. Powder-smoke headache from the use of giant powder is the most frequent acute trouble, causing serious congestive symptoms, headache, muscle twitching, nausea, vomiting, etc. Handling giant powder will also cause headache and may give rise to severe conjunctivitis and edema. This is best relieved by a combination of acetanilid, citrated caffeine, soda bromid and gelsemium. Sudamina is another acute trouble which he has seen. The chronic troubles are more serious. Chronic laryngitis is the most frequent, due largely to a peculiar manner of expelling air from the lungs practiced by miners; as nearly all miners are mouth breathers, the cold and dust-laden air thus increases the trouble. Chronic bronchitis tends to produce miners' consumption, which is only a step along the same line. Coleman also notices miners' nystagmus, though he does not call it by that name, probably not being familiar with the accounts of the condition given elsewhere. The constancy of the work, Sundays and weekdays, also tends to wear the miner out. For some time Coleman has been making urinary tests for mineral poisoning and has undoubted evidence of general systemic poisoning by anti-mony, arsenic, copper and lead.

**146. Amebic Dysentery.**—Osler has had a number of cases of this form of dysentery in the Johns Hopkins Hospital, sometimes three, four or five from the same locality, mostly males and few colored. It is a disease of the adult. More than 5 per cent. of the cases were in the third and fourth decade of life. The tendency is to become chronic. Very few cases die of dysentery itself, but it drags on for months or years with alternating periods of constipation and diarrhea. The most important and serious sequel is liver abscess. It is quite distinct from the bacillary form, less epidemic, rarely as acute, more chronic and liable to recurrence, the ameba are present in the stools, and lastly, and this is a very important point, it lacks the reaction of the Shiga bacillus.

**147. Bacillary Dysentery.**—The conclusions which Flexner deduces from the data available are: "1. The acute dysentery of Japan, Philippine and West Indian Islands, of Germany, and the United States is due to bacilli indistinguishable from each other. 2. Certain cases of chronic dysentery owe their beginning to the same organism. 3. The sporadic and institutional outbreaks of acute dysentery are caused by bacillus dysenteriae, and this organism is identical with that causing epidemic acute dysentery. 4. The acute bacillary dysenteries are attended by diphtheritis and ulceration of the intestine. 5. When diphtheritis complicates amebic dysentery a mixed or terminal infection with the bacillus of dysentery is to be suspected."

**149. Ipecac in Dysentery.**—Woodhull holds that ipecac is as specific in dysentery as quinin is in malaria, but it must be given in the proper way. The patient must be recumbent, the stomach empty, and about twenty minutes before giving the ipecac it would be well to paint the epigastrium with tincture of iodine or apply a mild sinapism sufficiently to induce gentle counter-irritation. Ten or fifteen minims of laudanum may be given, followed in ten or twelve minutes by 15 to 30 or more grains of ipecac in pill form or as a paste with very little water. No fluids should be taken for at least four hours and the recumbent position strictly maintained. The opium may be given with the ipecac in pill form. The size of the dose of ipecac should be in proportion to the gravity of the case. Sixty grains is not a maximum dose for an adult, but in the ordinary acute tropical dysentery 15 to 20 grains will suffice.

**152. Treatment of Dysentery.**—Hare reviews the different treatments, first, the ipecac method, which is proven to be of value by observers in the tropics. So far as we know, the effect seems to be largely by the production of a more profuse flow of bile. After the vomiting from the large dose, small

doses of three grains are given every hour and continued until a profuse, black, tarry stool is passed, which is considered a favorable sign, the vomiting being controlled by opium. It also relieves tenesmus and pain. While stimulants may be required, it is advisable not to use alcohol because of its action on the liver. Another plan is the purgative, which has been brought forward from experience in the Philippines and in South Africa. The bowels are first thoroughly moved with Epsom or Rochelle salts, and then aromatic sulphuric acid is given freely, so that it will exercise its well-known astringent or constipating influence. This is a more rational plan than the ipecac treatment, as it is well known that the micro-organisms in the intestines in dysentery are destroyed or rendered inert by an acid medium. The third plan of treatment mentioned consists in the use of intestinal antiseptics, bismuth salicylate, benzonaphthol, salol, calomel, etc. An antiseptic influence of the mercurial, however, is probably unduly accredited with the effect produced, the real value of calomel being that it increases the activity of the liver, both in destroying toxic material and in secreting bile. He does not use bismuth or salol as intestinal antiseptics to the exclusion of the salines or ipecac. Local treatment is often necessary. Clysters which will reach far up into the descending and transverse colon are necessary. Hare has found sulphocarbonate of zinc in the proportion of 20 gr. to the pint very satisfactory if used in this way. The method of making the injection is important. It should not be by means of a pumping syringe, but by a fountain syringe or surgical irrigator and the pressure never be over two or three feet, the injection being gently given, prolonged for ten, fifteen or twenty minutes. Where there is great bowel irritability it is well to use two catheters so as to facilitate the return flow and prevent bowel distension. Hygienic and dietetic methods have their place in the treatment. In conclusion, he mentions the need of active measures to aid the kidneys in elimination and the employment of antibacillary serum in the treatment of dysentery in Japan. This is not an antitoxic serum but an antibacterial one. Still another form of combating dysentery is by injecting quinin in the strength of 1 to 5000 high in the rectum to destroy the ameba. This seems to be as rational as the use of quinin in malaria, and it is hoped that a similar agency will be found to destroy the Shiga bacillus as quinin does the ameba.

**155. Prostatic Hypertrophy and Hemorrhoids.**—Three cases are reported by Townsend, who thinks there was a connection between aggravation of prostatic inflammation and enlargement and the operation for hemorrhoids. He says he may be mistaken, but he thinks the subject is one of sufficient importance to receive attention. Obliteration of the circulation, the disturbance and further congestion of the already chronically inflamed area are likely to produce, he thinks, acute prostatitis where the chronic congestive condition already exists.

**166. Calcium Sulphid.**—This substance is found of value in various skin diseases with glandular activity and suppurative conditions, especially in combination with nuclein. In disorders of the mucous membrane, especially uterine catarrh, it is well to combine with alkaline-saline medication, for its general systemic effect, together with strychnin arsenite to restore the muscle tonus. The physiologic properties are summed up as lymphatic glandular stimulant, anti-suppurative and resolvent. The conditions to which it is therapeutically applicable are suppurative conditions, boils, abscesses, carbuncles, smallpox, catarrhal affections, bronchitis, cystitis, laryngitis and skin eruptions arising from suboxidation. Aulde gives a long list of remedies that are valuable in collateral and alternate treatment, such as aconitin in neuralgia, anemonin in uterine catarrh, arsenic, arsenic bromid, etc.

1. Vaccination.—Acland's address made before an assemblage of hospital patrons and subscribers is adapted to the laity rather than the physician. Some of his points, however, are worthy of note. He gives elaborate tabulated statements showing the advantages of vaccination and that the decrease in the death rate of children has been mainly since the general practice of vaccination was adopted, the decrease in other diseases to which infants are liable being slight or nil, often increasing in some respects; as in summer diarrhea. He reviews the different objections to vaccination and refutes them, and points out that all the accidents in several million vaccinations would not equal the difference it has made in the deaths from smallpox in one year. He also points out that the vaccinated and revaccinated employes of smallpox hospitals are almost absolutely exempt from the disorder. His tabulations and illustrations are absolutely convincing in behalf of vaccination. They all show the same thing in different ways: 1. That the vaccinated are less liable to attack after exposure to smallpox. 2. They are less liable to suffer severely and to die from the attack. 3. Where ages are specified they show that the maximum protection among the vaccinated is found in the early years of life, and that the maximum incidence of smallpox among the unvaccinated is in childhood, and the maximum protection by vaccination is in the early years of life; hence the importance of early vaccination in infancy. He remarks that it is strange that a state which is so strict about its health, that it must label oleomargarin, etc., should be so neglectful in some respects as regards this much more important matter.

3. Caisson Disease.—The experience of the Greenwich foot-way tunnel with caisson disease is reviewed by MacMorran. Selection of the men was carefully made and the total percentage of rejections, both primary and secondary, was 18.8 per cent. The exemption from serious caisson disease was considered to be due to the ample supply of fresh air. It was found that a large percentage of those who had previously worked under similar conditions had a much lower pulse rate than the newer men and did not perspire nearly so freely while at work. They also showed a deviation from the normal in heart sounds, usually in the pulmonary area, but often in the aortic, but in several of these the heart sounds became absolutely normal after they had worked in compressed air for a few days. This he thinks bears out the fact that the best and most satisfactory remedy for a person suffering from caisson disease is to put him back into compressed air, and shows also the absolute necessity of the medical lock. He has never before heard of such an abnormal condition of the heart being thus got rid of, and he thinks that men who have previously worked under

such conditions should be more carefully examined than others. The pathology of the condition is rather obscure. We know, however, that the presence of carbonic acid gas in undue proportion in compressed air causes increase in the caisson disease. MacMorran believes that men whose eliminatory functions are impaired or sluggish are more or less liable, hence the rejection of a certain proportion who have showed signs of alcoholism and obesity. For the same reason, attention to the condition of the liver, kidney and stomach, as shown by the pulse and tongue, is of as great or greater importance than attention to the heart conditions. The increase of  $\text{CO}_2$  must act more seriously on some men than on others. He believes also in the pathologic effect of the hyperemia of the deeper tissues due to extra pressure, especially on the function of the vasomotor and sympathetic symptoms, though this idea is not generally accepted by authorities. As regards treatment, he finds nerve sedatives, such as bromid, especially ammonium bromid, are better than opium and in some severe cases of pain cannabis indica gave great relief. Potassium nitrate, potassium acetate, and ammonium acetate are good in the convalescent stage, or when the pain diminishes, but may be given from the first with good results. But by far the best treatment is the medical lock, into which, however, the purified air should be pumped until the pain goes, and then the pressure very gradually reduced. To effect this there should be attached to the medical lock an apparatus containing caustic soda in screens over which the air in passing would give up most of its  $\text{CO}_2$ . Most forms of caisson disease can be prevented by getting rid of the  $\text{CO}_2$  where it collects most, that is, at the shield in front where the men are working. All new men should be examined after work each day for a week, and those who are indisposed kept above ground until well.

**4. The Cocain Habit.**—Bose gives an interesting account of the cocain habit as observed in Calcutta. He finds its exhilarating effect very temporary and quickly followed by depression. The habit is quickly acquired and very difficult to abandon. He thinks the depression of spirits is more imaginary than real, as he has not noticed any fall of temperature or slowing of pulse, but the respiration becomes slightly hurried. The teeth and tongue of confirmed cocain eaters become jet black, probably due to the chemical change produced by the action of lime and saliva on the drug. The habit increases on one very rapidly. It was noticed in one case that the dose was raised from 1 to 12 gr. in a month. Unlike opium, it produces insomnia and anorexia, soon followed by dyspepsia and diarrhea. The dyspepsia of a cocain inebriate is very obstinate and prolonged use of the drug brings on deafness. The quantity of urine is diminished, delusions and hallucinations often occur and sometimes acute mania which is not amenable to treatment. He reports a number of cases and from analysis finds that the action of cocain on the nerve centers is slightly stimulative, but this is very temporary, followed by a feeling of depression, which gradually passes into complete lethargic inertia. The power of control is gradually lessened. The virile power is lost, with depression of the heart and vascular symptoms. The cardiac action is irregular and the circulation becomes languid. The loss of appetite and the failure of the digestive power is marked and emaciation follows. The craving for the drug increases. The elimination is impaired, depressing the function of the brain and causing insomnia and loss of memory. The toxic symptoms are not observed as long as moderate doses are used, but the person soon becomes a useless member of society and life becomes a burden to him. The only remedy is to lock him up and forcibly withdraw the drug.

**8. Typhoid Fever.**—This third lecture by Corfield goes over the evidence of the infection of typhoid fever by foods, especially shellfish, and its distribution through sewage.

**10. Puerperal Eclampsia.**—Herman discusses the statements made in certain text-books that the proper treatment for puerperal eclampsia is emptying the uterus. He gives statistics which he tabulates from various authorities, showing many cases with eclampsia after artificial delivery. If artificial delivery was satisfactory the treatment by Cesarean section

would be especially so. It is the quickest possible method, but the facts are that the fits are liable to continue after it and the evidences of the good effects of delivery are far from decisive. He lays stress on the importance of the rise of temperature and the quick pulse as unfavorable prognostic signs. He believes in the good effect of abstraction of heat by baths and the promotion of diaphoresis. He reports a case in which the tepid bath seemed to be very effective.

**11. Smallpox.**—The dangers from smallpox hospitals to the vicinity and the air-borne conduction are discussed by Thresh, who finds from the results of his investigation of certain local epidemics attributed to the Purfleet hospital ships: "1. That among the cases which occurred in Purfleet, both in the present and preceding epidemic, there was a large proportion which could not be traced to pre-existing cases. 2. That all the usual factors tending to produce epidemic prevalence of smallpox were present in the Orsett Union, with the addition (save in the case of Purfleet) of an unusually large proportion of unvaccinated children under ten years of age. 3. That none of these usual factors are capable of explaining the peculiar distribution of the disease during the epidemics investigated. 4. That all the results point to some central continuous focus of infection corresponding exactly in position with the smallpox ships. 5. That most careful inquiry fails to show any means whereby this continuous flow of infection can occur except on the hypothesis that it is air-borne. The extent of the area around a smallpox hospital which may be affected directly and indirectly by the hospital is apparently much larger than has hitherto been supposed. In the case of the ships lying off Purfleet the influence is probably being felt at a distance of fully three miles, and the presence of a belt of water half a mile in width is powerless to arrest the contagion. There can be no doubt that the danger increases with the increase of the number of acute cases in the hospital (the infectivity not being marked until a certain degree of concentration is reached) and with the proximity to the hospital. With a small hospital, say one constructed for from 10 to 30 cases, my impression is that there is but little danger of the disease being spread therefrom, providing the site is such as corresponds to the requirements of the local government board; but the danger can not be said to be non-existent. With hospitals having 100 or more beds, the danger is naturally much greater and, when we come to hospitals of the size of those required to cope with an epidemic in a large city, the peril may be great indeed." He thinks the aggregation of a large number of smallpox patients is a serious danger to the neighboring community. His idea of isolation is scattering the patients over large areas in properly constructed and equipped tents, with a central permanent administrative building.

**17. Dental Origin of Alopecia Areata.**—In Jacquet's 273 cases of alopecia areata, which he traces to some lesion in the jaws or teeth, 37 of the subjects were between 3 and 7; 79 between 7 and 14; 22 between 14 and 19, and 68 between 19 and 30. The largest numbers correspond to the various phases of dentition. He is convinced that some excitation of the buccal terminals of the fifth nerve induces the alopecia at certain connected points. The region of the back of the neck, mastoid and lower jaw forms the special irritable zone. His cuts show the routes traveled by the excitation to induce the corresponding patch of alopecia. These patches are not located over the nerves but in the parts where the innervation is comparatively deficient. The morbid stimulus is reflected to the point of minimal cutaneous innervation. The alopecia vanishes with the healing of the dental lesion. The local neurotrophic cause requires a predisposition or the alopecia does not follow. Jacquet is so thoroughly convinced of the neurotrophic, non-parasitic nature of alopecia areata that he offers to allow himself to be inoculated in the scalp or beard from the most virulent case that Sabouraud and Hallopeau can produce.

**20. Study of Cacodylic Medication.**—Burlreux has been making a careful study of cacodylic medication during the last year or so and proclaims that it can not be compared with arsenical medication. The arsenic in this combination has

nothing in common with the arsenic of arsenical compounds, neither from the chemical, the toxicologic nor the therapeutic point of view. He never encountered any evidences of an idiosyncrasy to the cacodylates, and they all seem to have approximately the same therapeutic effects. He prophesies a brilliant future for the therapeutic application of quinin cacodylate in intramuscular injections.

**24. Dangers of Internal Antisepsis.**—Robin reports two cases which conclusively establish that saturation of the organism with mercurial compounds does not prevent contagion from the typhoid bacillus and pneumococcus and does not attenuate their virulence. It even seemed to be responsible for the extreme severity of the infection in both cases. The patients were healthy young women with recent syphilis. One took .75 gm. of mercury in fifteen days, including .04 of the benzoate in subcutaneous injections, .41 gm. of the bichlorid in pills and the balance in metallic mercury, also in pills. There were three cases of typhoid fever in the same ward, and this intense mercurial treatment did not prevent infection. It assumed a grave form from the first, and gangrenous phlyctenæ and phlegmatia alba dolens developed the nineteenth day, with death two days later. The other case was a similarly virulent broncho-pneumonia.

**26. Gold in the Treatment of Tabes.**—Antonelli affirms that specific treatment has little chance of favorably influencing the course of tabes and ataxia except in cases of recent syphilitic infection. He believes that far better results can be obtained from tonic and "disintoxicating" medication and reports ten cases of old, inveterate tabes, rebellious to mercurial or iodid treatment, which were cured by a course of the tonic which he recommends. His formula is said to have been first used by the famous Cagliostro and has been handed down in certain families as a magic stimulant. Discarding the superfluous ingredients, he found that the active substances were phosphoric acid and gold. He combines these in his formula, using phosphovinic acid and gold oxid in the form of gold phosphovinate. The gold in this combination is antiseptic and antitoxic, fully equal to iodine in this respect and surpassing it in its tonic properties, which are especially concentrated on the nerve cells. He alternates or combines it with progressive doses of metallic iodine. In one case described at length, the ataxia had lasted for eight years, and the patient had been under Charcot's care for three. Mercurial and bromid treatment proved completely ineffectual. The patient could not walk without crutches and could neither eat nor dress alone. At the end of two years of regular treatment with the gold and iodine the crutches were discarded and he now walks nearly four miles a day, plays the violin and carves wood. In another case, eight months of regular treatment were followed by a complete cure. Antonelli recommends this simple stimulating and tonic treatment for all cases of tabes rebellious to or aggravated by ordinary treatment.

**28. Relations Between Dry Angina and Kidney Disease.**—As early as twenty years ago Joal called attention to the value of sore throat of the dry type as an early sign of kidney disease. Experience has confirmed the importance of this sign even before the appearance of albuminuria or other symptoms of the kidney trouble. The chronic pharyngitis in these cases has no distinctive characteristics which differentiate it from other affections of the throat occurring in the course of nutritional disorders or in the aged, but the dryness and absence of any inflammation of the nasopharynx or nasal fossæ should always suggest the possibility of insidious Bright's disease in such cases. Usually the patient has long been troubled with his throat and has been treated for cough, hoarseness, etc. The ordinary pharyngitis becomes gradually transformed under the influence of the kidney disease into the dry type with slow hypertrophy of the pharyngeal mucosa yielding later to atrophy. The mucosa becomes gradually greyish and dry at certain points in marked contrast to the congestion of the velum and anterior pillars. There is no pain, but the sensation of dryness in the throat impels to frequent drinking. The subjects are those predisposed to Bright's disease, but especially smokers.

**31. Mechanical Predisposition to Tuberculosis.**—Hollaenders experience has demonstrated that any lesion obstructing the free passage of air through the nose induces a predisposition to tuberculosis on the part of the upper air passages. The bacilli invariably locate in the recesses where the current of air is least felt. The lack of ample facilities for breathing in case of lupus of the nose explains the frequent descending tuberculosis of the upper air passages in such cases. He has witnessed the recurrence of a healed lupus of the nose when the breathing was obstructed from defective rhinoplasty. He has been very successful in averting recurrence since he has abandoned the attempt to provide a septum in restoring the nose after lupus. He now restores the nose with a single opening and finds that the results are most excellent from every point of view, cosmetic, functional and in the prevention of recurrence of the tubercular affections of the upper air passages. The latter heal when respiration is unobstructed and normal respiration restored. The photographs of his patients confirm his statements.

**32. Syphilitic Stenosis of Small Intestine.**—Rosenfeld emphasizes that when symptoms of stenosis of the small intestine are observed, syphilitic antecedents should be carefully sought, especially when tuberculosis can be excluded. Specific treatment must be energetic and prolonged. He reports one case of an architect of 28 who recovered by this means. In another case a man of 46 recovered spontaneously, but with strictures requiring resection of 10 cm. of the gut.

**36. The "Dilution Test" for Functional Diagnosis of the Kidneys.**—Illyes remarks that correct appreciation of the functional capacity of a single kidney is only possible when the ureter catheter is left in place a long time. He recommends a new means of testing the kidney which may effectively supplement other measures and afford information unattainable by any other means. It is the determination of the behavior of the kidney after ingestion of large amounts of fluid, that is, a test of its water-secreting function. In health, the osmotic pressure of the urine, in comparison with the freezing-point, is considerably higher than that of the blood. This capacity of the kidneys to increase the osmotic tension of the urine depends upon its water-absorbing capacity. If the parenchyma becomes inflamed, the secreting level is depressed and constant, that is, the normal independence between the elimination of solid molecules and the water diuresis is restricted within narrow limits. In interstitial inflammation, on the other hand, the diluting capacity of the kidney may be more or less normal. Research on ten patients after they had ingested nearly two quarts of water (Salvator), confirmed the significance of these facts in clinical diagnosis. The urine was drawn from each ureter every half hour. This prolonged use of the catheter does no harm, he is convinced. The first irritation from it soon subsides. The secreting faculty of the kidney may be entirely suspended or only diminished. The points in diagnosis are the delay in the appearance of the increased secretion of urine, the difference in the amount secreted by each kidney and the relative proportion of molecular concentration in each urine, as determined by the freezing-point. In one typical case the left kidney did not respond to the excessive amount of fluid ingested, but the right kidney seemed to be functionally sound. The "dilution secretion" made its appearance in less than an hour; it lasted two and one-half hours; the freezing-point was 1.75 and the phloridzin test was also positive. The freezing-point of the blood was 0.61, which indicated renal insufficiency, and traces of pus were found in the urine, consequently the removal of the pathologic kidney was not advised.

**37. Treatment of Weakly Children.**—Ritter believes that any lack in the salts in the body entails a corresponding loss of energy, especially in children whose supply of lymph is much larger in proportion than in adults. He describes his measures of general hygiene to increase the resistance of weakly children: arms, legs and feet bare and linen garment for the summer, on a dust-free lawn, with sand baths, etc. The diet includes lipanin and malt extract, with 2 per cent. lime and 5 per cent. iron. He found that the vitality of dogs became depressed

when deprived of salts and that they recovered their vigor when the normal amounts were supplied. He thinks that malt extract owes its chief value to the salts it contains.

**40. Contribution to Our Knowledge of Cholelithiasis.**—Boas asserts that atypical cases of gallstone colic or cholecystitis are very rarely correctly diagnosed, and that few attempt to differentiate between cholelithiasis and cholecystitis or cholangitis or the results of secondary adhesions. In 1894 he published in his manual that the area of tenderness in cholelithiasis was in the region of the twelfth thoracic vertebra, two or three finger breadths to the right of the spine. It frequently extends further to the right, sometimes to the posterior axillary line. On the left side there is little if any tenderness. Besides this local sensitive area, the region over the entire posterior surface of the liver may be sensitive. This diffuse tenderness may persist for weeks and months after the attack. His statements did not attract general attention at the time, but their correctness has been more and more confirmed by his further extensive experience. He now distinguishes three areas: the margin of the liver and the region of the gall-bladder, the subcostal portion of the liver, and its posterior surface. The area of tenderness in the back is liable to occur during an acute attack and persist long after it has subsided. It may exist in the latent stage of cholelithiasis as a sign of attacks passed through, possibly years before. The sensitiveness in the back does not necessarily parallel the sensitiveness of the margin and gall-bladder area, but may persist long after the latter has vanished. His experience has also shown that certain cases are unaccompanied by any tenderness in the back either in the acute or in the latent stage. These local manifestations are possibly due to a diffuse perihepatitis proceeding from a cholecystitis or pericholecystitis. He finds that the most reliable method of testing the sensitiveness is by Faradization, applying the electrodes to corresponding portions of both sides of the back, commencing with a very weak current, and increasing to a maximum of 4 to 6 milliamperes. A tingling on the liver side is frequently felt before any sensation is experienced on the other side, and it increases to severe pain, while the left side is only slightly if at all painful. The Galvanic current answers the same purpose, applying the anode on the right and the cathode on the left side. This test is by no means an absolute sign of the absence or presence of cholelithiasis, but it points with certainty to the liver as the origin of the trouble, and even this is a great gain in diagnosing. The complete absence of tenderness in some cases and its intensity in others may prove important means of differentiating if those who have opportunity for such observation will make a special study of the conditions noted in operating on such cases. Boas thinks that patients with a tendency to cholelithiasis should be kept permanently under observation and impending attacks warded off. He considers 200 to 300 gm. of Carlsbad waters taken daily for six months, an excellent means of keeping it in the latent stage. The diet should avoid articles tending to induce constipation or obesity. He advises loosening or removing the corset after meals—its complete banishment it is hopeless to expect for the present, he observes. He also endorses Möbius' recommendation of ten minutes devoted to deep breathing three times a day with the chest and abdomen bare. He warns against massage, as he has witnessed numerous cases in which the cholelithiasis was aroused by it from the latent stage. He therefore never orders massage of the abdomen for a woman without enquiring in regard to preceding cholelithiasis and ascertaining if there is any sensitive liver area. By examining the three areas mentioned above he has found it possible to follow the gradual extinction of the tendency, and not until the last trace of tenderness has vanished does he consider his patients cured. He has also found it possible to watch over his patients by repeated examination of these areas and detect an impending attack by increased tenderness long before it is heralded by any other symptoms.

**43. Refractometric Examination of the Blood.**—The JOURNAL has previously mentioned Strubell's method of investigating the composition of the blood by its refracting power. A single drop will suffice and the results have proved so constant

and significant in his three years of testing the method that he now recommends it as a simple, practical and valuable means of determining the composition of the blood. He uses Petrich's refractometer which he described in his previous communication in the *Deutsche Arch. F. Klin. Med.*, lxi. The refracting power of the blood does not convey the same information as the determination of the freezing-point, but it indicates unerringly the proportion of albumin in the blood. The water has a refracting value of about 15 marks on the graduated scale and the salts in the blood an additional 3 marks. Deducting 18 marks on this account, the remaining marks on the scale are divided by 4.2, which is the refracting value of 1 per cent. of albumin, and the quotient is the exact amount of albumin contained in the serum examined. The varying proportion of salts renders this abbreviated test impracticable for the urine, but it can be applied to capillary amounts, although there is a possibility of error in this case. He proclaims that this determination of the refraction exponent is destined to prove a valuable acquisition to our means of clinical diagnosis of the blood.

**44. Improved Method of Percussion.**—Instead of using the hand or several fingers, Plesch uses a single finger for percussion, bent exclusively in the first interphalangeal joint, the rest of the hand horizontal and parallel to the surface to be examined. He taps with the middle finger of the other hand on the distal epiphysis of the bent finger. The vibrations induced in this way cause the percussion sounds to be peculiarly distinct and allow the delimitation of organs with a hitherto unattainable precision.

**45. Antipyrin in Puerperal Fever.**—Curschmann reports that antipyrin seems to have an especially favorable, almost specific action on septicæmic conditions, especially the puerperal. He gives it in .5 gm. doses, to a daily total of 2 to 4 gm., and finds that a drug exanthem does not contra-indicate its further use. Half of his 78 cured cases during the last ten years were treated with antipyrin in this way, out of a total experience of 174 cases.

**51. Prevention and Internal Treatment of Biliary Lithiasis, Etc.**—Clemm cites various writers to the effect that fats stimulate the production of bile, the albuminoids nearly as much, while the carbohydrates have only a slight influence in this respect. The effect of the fats is felt for three to six hours. The fondness of women for carbohydrates suggests an explanation for the greater prevalence of biliary lithiasis among them. Prevention and treatment should be along these lines. The best means of administering fat is in the form of sodium oleate, better known as eunatrol. It requires no further saponification in the intestines, and is readily taken in the form of an emulsion of 10 gm. eunatrol and 5 of tincture of valerian in 150 of peppermint water with 20 drops of essence of pineapple. Tests *in vitro* demonstrated that eunatrol has a most remarkable dissolving power, besides the cholagogue property to which it owes its fame. Clemm asserts that this treatment will cure all cases of pure cholelithiasis, even obstinate ones. He orders as preventive measures a glass of milk with a slice of bread and butter at bedtime, albuminoids with the breakfast, exercises in deep breathing, and in case of an established lithiasis a tablespoonful of eunatrol at breakfast, lunch and bedtime. This is kept up for four to six weeks after the severer symptoms have subsided, omitting the midday dose and continuing the bedtime dose for three months.

**53. Treatment of Croup.**—Bayer has treated twenty cases of croup without a mishap since he instituted treatment with calomel and apomorphin. He gives 2 eg. of calomel every two hours, alternating it with a tea-spoonful of a mixture of apomorphin, 1 eg. in 100 gm. water, with two drops of dilute hydrochloric acid and 10 gm. of simple syrup. After the first severe symptoms have subsided he suspends the calomel for a few hours during the day, but keeps it up at night. Even as late as the second or third day or a little later, the chances are still favorable. Improvement is marked in twelve hours. In three to five days the threatening symptoms subside. Local measures can be omitted.

**54. Colloid or Soluble Mercury.**—Werler lauds colloid mercury as the most effectual and convenient method of anti-syphilitic treatment by the general practitioner. A 10 per cent. salve of this soluble mercury is absorbed through the skin far more rapidly and thoroughly than any other preparation of mercury in vogue. It is mild, non-irritating and non-toxic. He prefers it even for internal administration. The mercury in this form is eliminated very slowly, regularly and gradually.

**56. Four Hundred Operations for Urinary Calculi.**—Frisch observes that he can not imagine any case of lithiasis vesicae in which the high operation would not perfectly answer the purpose. It never fails even in the severest and most complicated cases, but on account of its dangers, it should not be used indiscriminately. The old mortality of 30 to 40 per cent. has dropped to 13 and 20 per cent., but Guyon reports a mortality of 28 per cent. during the last ten years. In Frisch's cases the mortality was 12.7, while that of lithotripsy was only 2.6 per cent. Contra-indications for the latter are an unusually large stone, preventing the free movement of the instrument, or unusual hardness or firm impaction, an unbreakable foreign body and cases of cystitis complicated by a renal affection, rebellious to preliminary treatment. Perineal incision is much less dangerous than the high operation, but even its advocates report the disadvantages of long protracted healing and the liability to a persisting fistula. Frisch performed 84 high operations under chloroform and 10 under cocaine anesthesia, preceded half an hour before the operation by an antipyrin rectal injection. This combination proved very efficient—the patients experienced scarcely any pain. In 4 cases he was compelled to establish a fistula on account of retention from hypertrophy of the prostate, and 2 have been permanently cured of the tendency to bladder lithiasis. In 2 others the formation of phosphate calculi continued, but they were readily extracted without narcosis by merely enlarging the fistula. In 4 patients with complete retention he removed the middle lobe of the prostate with the thermocautery after extracting the calculi. Two were cured, but the intervention had no effect on the others. In 2 instances stones developed with a ligature thread for the nucleus a year after the extirpation of a papilloma of the bladder. In 2 patients the stones developed around a cast-off piece of the scab from a Bottini incision of the prostate. In two cases in which aspirating drainage had been established a hernia developed at the point of the high operation. The 12 fatal cases in the 94 treated by the high operation included 6 out of the 12 in which the bladder had been left open, 4 out of the 38 treated by aspirating drainage, and 2 out of the 44 in which the bladder had been completely sutured. These groups correspond to the severest, the moderately severe and the lightest. Death was due to pneumonia in 2 instances, to pyelonephritis in 5 and to embolism of the lungs in 1; 2 other patients succumbed to their extreme exhaustion; 1 to the chloroform and 1 to the sudden emptying of the bladder in a case of chronic incomplete retention. The latter patient was a man of 63 who refused intervention for more than a year after symptoms of calculi had developed. The bladder reached to the umbilicus. The slightest movement caused intense pains in the bladder region, and the urine trickled night and day. The prostate was in the third stage of enlargement. The patient was anemic, emaciated, tongue dry and thirst excessive. Intervention seemed dangerous, but delay was out of the question and the high operation was performed under cocaine and the bladder drained and tamponed. The urine was bloody that evening and the next day. Only 400 c.c. of dark red urine was evacuated the second day and the patient died with symptoms indicating that not only the hemorrhage but the sudden disturbance in the renal function by the changes in the compression were responsible for the fatal termination. The shape of the stone explained the pains experienced, as it was covered with sharp projecting points. In another case the stone was nearly round and fitted into the fundus with two deep holes opposite the orifices of the ureters. Nineteen patients were operated on twice; 6, three times; 3, four times, and 3, five times. Recurrence was noted after the high operation in 22.3 per cent. and after lithotripsy in 9.8 per cent.

**64. Injury of Goiter from Contusion.**—Hertle refers to 2 cases of sudden hemorrhage in the goiter in young persons without appreciable cause. Withdrawal of the blood by puncture cured the patient and averted suffocation. In Maschka's case the hemorrhage in the goiter proved fatal in a few minutes. In a case of contusion personally observed a woman of 53 who had long had a goiter on the left side was thrown from a carriage. The goiter swelled and there was much difficulty in breathing and swallowing. The neck was much enlarged, the rear wall of the pharynx bulging. Puncture of the left side of the neck allowed the escape of a pint of dark hemorrhagic fluid. The swelling and difficulty in breathing and swallowing disappeared at once. Four days later the cyst was extirpated. It was as large as the head of a child and the walls were hard. A hole with ragged edges was found in the rear wall, and the fluid escaping from the cyst at the time of the traumatism had burrowed a passage behind the esophagus into the lower mediastinum. This passage was drained with long strips of gauze brought out through the wound. The patient has been in fine health during the seven years since. Pantlen has reported the case of a woman of 72 with an old, moderate goitre. It was hit by the elbow of another person, and she died immediately. About a pint and a half of hemorrhagic fluid was found in the right pleural cavity. An old work mentions the cure of a goiter which was pierced by a spear during the siege of Vienna. Billroth has reported a case in which the goiter perforated into the pharynx with pyemia and death. All the ruptures occurred in the rear wall. In a second case observed by the writer a patient with a medium struma fell down stairs. The neck swelled with symptoms of impending suffocation. A tear 4 mm. long was found in the inferior thyroid artery. The arteries were ligated and the goiter drained. The patient died the next day of heart failure, although no signs had indicated the involvement of the vagi. The symptoms had been the same as in case of rupture of a cystic goiter. Etienne has described a similar case in which death followed a slap on the goiter. The symptoms indicated compression of trachea and paralysis of vagus. The capsule was found lacerated with hemorrhage into the mediastinum and cellular tissue of neck. The experiences related indicate that the severest consequences may follow slight contusion of a goiter or may even occur spontaneously. In the operations it was noticed that the inferior thyroid artery always showed signs of arteriosclerosis even when the superior was still intact.

**67. Chloroform Icterus.**—Wechsberg tested the urine in 100 chloroform anesthetics and obtained a positive reaction for bilirubin pigments in 16. The bilirubinuria appeared in 6 the first day, in 8 the second and in 2 the third day. It lasted two days in 7, three days in 4, one day in 3, four days in 1 and five days in another. All exhibited subicterus, but none were febrile cases. In a few the bilirubinuria was not accompanied by any icteric symptoms. He believes that the disposition to icterus can be traced to some abnormal condition of the liver.

**70. Traumatic Lipemia.**—Fuchsig describes the case of a girl of 17 who jumped from a third-story window shattering a number of bones. At first the symptoms were not serious, but after a few hours convulsions and high temperature developed, with death in seventy-two hours. Droplets of fat were found in the vessels of all the organs examined. He produced somewhat similar conditions in animals by injecting fluid fat into the carotid. He found that about .5 c.c. passed directly into the vessels of the brain without entering other capillary systems. After an hour of quiet the animals were seized with fatal convulsions. The capillaries in the lungs were also gorged with the droplets without causing symptoms. The death was evidently due to paralysis of the vital centers from the fat in the cerebral circulation. The multiplicity of the symptoms in lipemia is probably due to the circulation of the droplets of fat in the blood and their arrest and accumulation at certain points where the current is sluggish. Every fracture of a bone is followed by more or less lipemia. The larger proportion passes through the lungs into the general circulation. The persistence of an open foramen ovale favors lipemia of the brain in particular, and this had been noted in the personal case

described. Between the extremes of physiologic and traumatic lipemia, is that induced by subcutaneous injections of oil for therapeutic purposes. No injury results from them as the amount of fat—even 200 gm.—is too small. It is taken up gradually into the circulation and part is eliminated or incorporated with the tissues.

**77. The Question of Spinal Braces in Lateral Curvature.**—Judson's article was published originally in *THE JOURNAL*, February 22, 1902, p. 508, which fact the translator evidently forgot to mention.

**34. Malarial Vertigo.**—Triantaphyllides maintains that besides the symptomatic vertigo of malaria there is a paludal vertigo which is in itself a morbid entity, a paludal neurosis. It may be intermittent or permanent or merely a condition of dizziness, or it may be associated with other neuroses, or the various forms may alternate. In a number of cases which he relates, the vertigo could be attributed only to the malaria. There was no anemia, neurasthenia or dyspepsia nor any other manifestation of malaria, and the vertigo could be cured at once by hypodermic injection of large doses of quinin for four or five days. It is probably due to alteration of the solar plexus by the malaria, similar to the gastric vertigo described by Trousseau. The vertigo usually ceases when the patients recline. In one of his patients compression of the sciatic and other nerve trunks induced the vertigo even when he was reclining. The differentiation of malarial vertigo is important, as it might easily be confounded with the vertigo in heart disease, syphilis and arteriosclerosis. The pallor, the reappearance of the vertigo on vigorous compression of the solar plexus, and the various solar paresthesias which precede or accompany the vertigo, all aid in the diagnosis. Patients with a tendency to ptosis of the viscera are relieved by an abdominal support, which also aids in the mitigation of the vertigo.

**85. Pathology of the Cells of the Sensory Ganglia.**—This progress report of Lugaro's experimental research is profusely illustrated. His previous communications were in the *Rivista*, v, 4, 6, and 9, and vi. 10. This part deals mostly with the effects of resection of the vagus and cervical plexus in rabbits.

**87. Palpation of the Pylorus.**—Obrastzoff describes nine cases in which the pylorus could be palpated as a cylinder or a knot, usually in the region of the right rectus. The cylinder lay horizontal or slanting, about the size of the forefinger or thumb. Both the cylinder and the knot would become soft under the fingers, subside and vanish in a few seconds, resuming this peristaltic play again in a few minutes, independent of whether the stomach was full or empty. A slight rumbling could be elicited sometimes by palpation, accompanied by a sound resembling the squeaking of a mouse. It was probably due to the return of gases or droplets of chyme forcing their way back into the resonant cavity of the stomach. As the cylinder or knot could be palpated from 4 to 8 cm. above the lower limits of the stomach, the idea that it might have been the transverse colon can be discarded. A dull tympanitic sound could be elicited on percussion of the liver in the region of the transverse colon with absolute flatness to the right on a line with the tumor. This tended to show that no gases passed with the chyme from the stomach into the duodenum. This phantom tumor at the pylorus is merely an exaggeration of the physiologic peristalsis. The pylorus contracts more vigorously in gastroparesis and in case of excessive acidity, on account of the resistance to the propulsion of the stomach contents into the duodenum. On the other hand, in another patient the peristaltic wave involved the whole stomach. The case was distinguished by complete paralysis of the secretory function in respect to ferments and hydrochloric acid, with eructations of gases belonging to the diamine group and a tumor in the pylorus and adjacent part of the stomach. During the peristaltic wave the outline of the greater curvature could be seen moving from one interspace to the other. Crepitation was felt on palpation and a friction sound could be heard. This might have been due to corrugation of the surface of the gastric serosa and the presence of a relatively large amount of serous fluid. Disappearance of this phenomenon with that of the tumor excluded the assumption of partial peritonitis in the

form of a perigastritis. The spasmodic contraction in the pyloric end of the stomach was evidently a motor neurosis accompanying the grave disturbances in the secreting function of the stomach in a neurasthenic patient.

**89. The Miser in the Great Russian Novel, "Dead Souls," as a Study of Senile Dementia.**—Tchizh reviews Gogol's classic portrayal of "Plushkin, the miser," and contends that he is not the normal type of a miser but a pathologic type of senile dementia. His avarice is not a psychologic but a pathologic phenomenon, accompanied by his loss of moral sense, indifference to his children, grandchildren and social opinion, his uncleanness, fear and distrust of every one, loss of the sense of taste and incapacity of experiencing either lasting joy or sorrow. He was in a state of constant apathy, with the exception of the sense of ownership of property. His mental faculties were so weak, especially his memory for recent events, that he was incapable of managing his affairs properly. He was unable to concentrate his attention, or distinguish between profit and loss, or appreciate the relative value of things. He lived wholly in the present; the future and outside interests did not exist for him. The sight of money and the remembrance of his bosom friend were the only things that could bring expression to his face. There was no purpose in his life. It was founded on his old habit of hoarding money, which he neither enjoyed himself nor allowed his children to enjoy. Habit accounts for his entire behavior. Gogol pictures the harm caused by such a man to society, to his family and to himself, and Tchizh urges a more rational attitude, based on the principles of psychiatry, toward this class of unfortunates to avoid the harm and suffering which they entail. If Gogol had written nothing else, he adds, this masterly representation of senile dementia would be sufficient to make his name immortal.

**97. Chloroform Water in Treatment of Typhoid Fever and Other Gastro-Intestinal Affections.**—Dibailloff reports as the results of extensive tests and experience, that chloroform water assuages thirst, soothes pain in the stomach and relieves nausea and vomiting. It is valuable, therefore, as a symptomatic remedy, but it is useless in chronic gastro-intestinal catarrh, and has no specific influence in typhoid fever, as some have asserted.

### New Patents.

Patents of interest to physicians, etc., April 22 and 29:

- 698,264. Hernial truss. George W. Derr, Philadelphia.
- 697,994. Making thymol. Maurice Dinesman, Paris, France.
- 698,399. Making magnesium peroxid compound. Franz Fuhrmann, Berlin, Germany.
- 698,270. Hernial truss. Wm. H. Garson, Philadelphia.
- 698,022. Electric massage machine. Edward B. Jacobson, Boston.
- 698,335. Coin-freed gymnastic apparatus. Karl Strauss, Wiesbaden, Germany.
- 698,079. Salicylate of salicyl quinln, etc. Heinrich Thron, Frankfurt-on-the-Main, Germany.
- 698,426. Abdominal bandage. Everett L. Abbott, New York City.
- 698,786. Sanitary spittoon. Napoleon J. Beaudin and N. R. Thibert, Worcester, Mass.
- 698,898. Nebulizer. Wm. and J. Boeckel, Philadelphia.
- 698,447. Syringe. Corydon I. Bush, Kansas City.
- 698,833. Optometer. Francis A. Hardy, Evanston, Ill.
- 698,704. Making hydrochloric acid. Edward Hart, Easton, Pa.
- 698,511. Syringe. Frederick H. Jones, Wakefield, Mass.
- 698,711. Sterilizing apparatus. George W. Kellogg, Hartford, Conn.
- 698,713. Appliance for assisting the hearing. Pauline A. Klawns, Melbourne, Victoria, Australia.
- 699,095. Hernial truss. Julius C. Le Hardy, Savannah, Ga.
- 698,861. Combined cushion, water bag and fountain syringe. John P. Schan, Brooklyn.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., April 24 to 30, 1902, inclusive:

Aristides Agramonte, contract surgeon, leave of absence for three months granted.

William B. Banister, major and surgeon, U. S. A., member of an Army retiring board at Washington, D. C., vice Major Edward C. Carter, surgeon, U. S. A., relieved.

Walter Cox, lieutenant and asst.-surgeon, U. S. A., to duty with

troops from the Department of California to the Department of Texas and thereafter to report to the Surgeon-General of the Army at Washington, D. C., for instructions.

Carl R. Darnall, captain and asst.-surgeon, U. S. A., on his arrival in San Francisco, Cal., will proceed to Plattsburg Barracks, N. Y., for assignment to duty at that post.

Charles L. Heizmann, lieutenant-col. and deputy surgeon-general, on his arrival at San Francisco, Cal., will proceed to Chicago, Ill., for duty as chief surgeon, Department of the Lakes, relieving Lieut.-Col. Timothy E. Wilcox, deputy surgeon-general.

Merritte W. Ireland, captain and asst.-surgeon, U. S. A., leave of absence for fourteen days granted.

Richard W. Johnson, major and surgeon, U. S. A., now on leave of absence at San Francisco, Cal., is relieved from further duty at Fort Douglas, Utah, and will report to the commanding general, Department of California, for assignment.

George B. Jones, contract surgeon, now at Angel Island, Cal., will proceed to Rushville, Ind., for annulment of contract.

Charles F. Kleffer, captain and asst.-surgeon, U. S. A., to report for duty with troops from the Department of California to the Department of Texas, and on the completion of this duty to report for assignment at Fort Screven, Ga.

Henry S. Kiersted, lieutenant and asst.-surgeon, U. S. A., leave of absence granted for two months, on account of sickness, with permission to apply for an extension of one month.

George A. McHenry, captain and asst.-surgeon, Vols., leave of absence for two months granted, to take effect on his arrival in the United States.

Edward L. Munson, captain and asst.-surgeon, U. S. A., to proceed to Millville, N. J., on business pertaining to the Medical Department of the Army, and on the completion of this duty to return to his station in Washington, D. C.

James E. Shellenberger, contract surgeon, from St. Petersburg, Fla., to duty at Fort Ringgold, Texas.

Allen M. Smith, captain and asst.-surgeon, U. S. A., leave of absence for fifteen days granted.

Henry D. Snyder, captain and asst.-surgeon, U. S. A., member of an examining board at Governor's Island, N. Y., during the temporary absence of Major William H. Corbuser, surgeon, U. S. A.

Louis A. Thompson, contract surgeon, now at Dayton, Ohio, is relieved from further duty in the Division of the Philippines and assigned to duty at Columbus Barracks, Ohio.

Victor E. Watkins, contract surgeon, from Fort Williams, Me., to duty at Whipple Barracks, Ariz.

Timothy E. Wilcox, lieutenant-col. and deputy surgeon-general, from duty as chief surgeon, Department of the Lakes, to Vancouver Barracks, Wash., as chief surgeon, Department of the Columbia, relieving Major Rudolph G. Ebert, surgeon, U. S. A.

Llewellyn P. Williamson, lieutenant and asst.-surgeon, U. S. A., former orders directing him to report for duty at Columbus Barracks, Ohio, amended so as to assign him to duty at Jefferson Barracks, Mo.

### Navy Changes.

Changes in the Medical Corps of the Navy, week ending May 3, 1902:

Asst.-Surgeon R. M. Young, detached from the Cavite Naval Station and ordered to duty at Guam, L. I.

Surgeon W. R. Dalrose, detached from the *Wisconsin* and ordered to the *Solace*.

Surgeon C. F. Stokes, detached from the *Solace* and ordered to the *Wisconsin*, and on arrival of that vessel at Puget Sound, ordered to the *Oregon*.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended May 1, 1902:

Surgeon Preston H. Buihache, detailed to represent the service at American Congress of Tuberculosis at New York, N. Y., May 14, 15 and 16.

Surgeon H. W. Austin, seven days' leave of absence from April 23, 1902, under paragraph 179 of the regulations.

Surgeon P. M. Carrington, detailed to represent the service at American Congress of Tuberculosis at New York City, May 14, 15 and 16, reporting at Washington, D. C., en route to New York, and on return to Fort Stanton.

P. A. Surgeon H. D. Geddings, detailed as supervisor of repairs and alterations of the steamer *Neptune*, at Baltimore, Md.

P. A. Surgeon J. C. Perry, relieved from duty as chief quarantine officer of the Philippine Islands, and directed to proceed to San Francisco, and await orders.

P. A. Surgeon A. R. Thomas, relieved from duty in office of U. S. Consul-General, at London, England, and directed to proceed to Manila and assume the duties of chief quarantine officer of the Philippine Islands, relieving P. A. Surgeon J. C. Perry.

P. A. Surgeon H. S. Cumming, detailed as inspector of unserviceable property at office of plague commission at San Francisco.

Asst.-Surgeon John McMullen, relieved from duty at Baltimore, and directed to proceed to Boston and report to medical officer in command for duty and assignment to quarters, relieving Asst.-Surgeon M. W. Glover.

Asst.-Surgeon S. B. Grubbs, Bureau letter of April 18, directing him to assume command of the Gulf Quarantine Station, amended so that he shall visit New Orleans, La., Pascagoula, Miss., and Mobile, Ala., en route.

Asst.-Surgeon H. B. Parker relieved from duty in the Hygienic Laboratory, and appointed chairman of Board of Medical Officers for the investigation of yellow fever, malarial fevers and dengue, at Vera Cruz, Mexico.

Asst.-Surgeon J. F. Anderson, to proceed to Norfolk, Va., for special temporary duty.

Asst.-Surgeon V. G. Helser, to proceed to Quebec, Canada, for duty in the office of the U. S. Commissioner of Immigration.

Asst.-Surgeon W. C. Billings, granted leave of absence for two months from May 1.

Asst.-Surgeon J. Goldberger, to report at Washington, D. C., for special temporary duty. Bureau letter of April 18, directing him to proceed to Tampico, Mexico, amended so that he shall visit

Norfolk, Va., New York City, Havana, Cuba, and Vera Cruz, Mexico, en route.

Asst.-Surgeon A. J. McLaughlin, upon being relieved from duty at the Immigration Depot by Asst.-Surgeon M. W. Glover, to proceed to Washington, D. C., and report to the director of the Hygienic Laboratory for duty.

Asst.-Surgeon M. W. Glover, upon being relieved from duty at Boston by Asst.-Surgeon John McMullen, to proceed to New York City, and report to Surgeon G. W. Stoner, Immigration Depot, for duty, relieving Asst.-Surgeon A. J. McLaughlin.

Asst.-Surgeon J. T. Burkhalter, to proceed to Scranton, Miss., for special temporary duty.

A. A. Surgeon R. F. L. Burford, granted leave of absence for thirty days from May 15.

A. A. Surgeon B. Kinsell, granted leave of absence for seven days from May 12.

A. A. Surgeon W. O. Wetmore, granted leave of absence for seven days from April 19, under paragraph 201 of the regulations.

### PROMOTION.

Junior Hospital Steward F. L. Gibson, promoted to the grade of senior hospital steward from June 11, 1901.

### BOARD CONVENED.

Board convened at Washington, D. C., April 28, 1902, for the physical examination of candidates for the position of second assistant-engineer, R.C.S. Detail for the Board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon B. S. Warren, recorder.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended May 3, 1902:

#### SMALLPOX—UNITED STATES.

California: Los Angeles, April 12-19, 3 cases; San Francisco, April 13-20, 3 cases.

Colorado: Denver, April 12-19, 7 cases.

Illinois: Belleville, April 19-26, 2 cases; Chicago, April 19-26, 13 cases; Freeport, April 19-26, 1 case; Galesburg, April 19-26, 1 case.

Indiana: Evansville, April 19-26, 4 cases; Indianapolis, April 19-26, 16 cases; Terre Haute, April 19-26, 4 cases.

Kansas: Wichita, April 19-26, 5 cases.

Kentucky: Covington, April 20-27, 16 cases; Lexington, April 19-26, 2 cases.

Louisiana: New Orleans, April 19-26, 1 case.

Maryland: Baltimore, April 19-26, 1 case, 2 deaths.

Massachusetts: April 19-26, Boston, 51 cases, 3 deaths; Brockton, 1 case; Brookline, 2 cases; Cambridge, 2 cases; Everett, 3 cases; Fall River, 2 cases; Fitchburg, 1 case; Malden, 1 case; Medford, 1 case; New Bedford, 3 cases; Newton, 4 cases; Somerville, 5 cases.

Michigan: Detroit, April 19-26, 5 cases; Ludington, April 19-26, 8 cases.

Missouri: St. Louis, April 13-27, 83 cases, 2 deaths.

Montana: Butte, April 20-27, 5 cases.

Nebraska: Omaha, April 19-26, 45 cases.

New Jersey: Camden, April 19-26, 3 cases; Hudson County, including Jersey City, April 6-27, 107 cases, 13 deaths; Plainfield, April 19-26, 1 case.

New York: Buffalo, March 27-April 30, 21 cases; New York, April 19-26, 56 cases, 13 deaths; Yonkers, April 18-25, 1 case.

Ohio: Cincinnati, April 18-25, 12 cases; Cleveland, April 19-26, 2 cases, 1 death; Dayton, April 19-26, 2 cases.

Pennsylvania: Columbia, April 21-28, 4 cases; Erie, April 19-26, 2 cases; Philadelphia, April 19-26, 31 cases, 6 deaths; Scranton, April 19-26, 6 cases.

Rhode Island: Providence, April 19-26, 2 cases.

Tennessee: Memphis, April 19-26, 14 cases, 2 deaths.

Utah: Salt Lake City, April 19-26, 1 case.

Washington: Tacoma, April 13-20, 3 cases.

Wisconsin: Green Bay, April 20-27, 6 cases; Janesville, April 19-26, 1 case.

#### SMALLPOX—FOREIGN.

Austria: Prague, April 5-12, 8 cases.

Barbados: April 12, 5 cases.

Belgium: Antwerp, April 5-12, 9 cases.

Canada: Quebec, April 12-19, 9 cases, 2 deaths; Winnipeg, March 29-April 19, 18 cases.

China: Hongkong, March 8-22, 7 cases, 7 deaths.

Colombia: Panama, April 21, present.

France: Rheims, March 31-April 6, 5 cases, 3 deaths.

Gibraltar: April 6-13, 1 case.

Great Britain: Dundee, April 5-12, 1 case; Edinburgh, April 5-12, 1 case; Glasgow, April 11-18, 11 cases, 2 deaths; London, April 5-12, 274 cases, 73 deaths.

Greece: Athens, April 5-12, 1 case.

India: Bombay, March 25-April 1, 10 deaths; Karachi, March 23-30, 5 cases, 2 deaths.

Italy: Palermo, April 5-12, 40 cases, 5 deaths.

Mexico: Vera Cruz, April 12-19, 5 cases, 2 deaths.

Russia: Moscow, March 29-April 5, 14 cases, 3 deaths; Odessa, April 5-12, 3 cases; Warsaw, March 29-April 5, 2 deaths.

Spain: Corunna, April 5-12, 1 death.

Uruguay: Montevideo, March 8-15, 71 cases, 5 deaths; Montevideo, March 22-29, 70 cases, 3 deaths.

#### YELLOW FEVER.

Mexico: Vera Cruz, April 12-19, 12 cases, 5 deaths.

Venezuela: Puerto Cabello, Feb. 8-15, 1 case, 1 death.

#### CHOLERA.

China: Canton, March 19, present, 9 deaths among Europeans; Hongkong, March 8-22, 23 cases, 19 deaths.

India: Bombay, March 25-April 1, 3 deaths.

#### PLAGUE—FOREIGN.

China: Canton, April 24, malignant outbreak; Hongkong, March 8-22, 1 case, 1 death.

India: Bombay, March 25-April 1, 909 deaths; Karachi, March 23-April 30, 119 cases, 92 deaths.

Zanzibar: Nairobi, March 20, 20 cases, 5 deaths.

### THE TREATMENT OF INOPERABLE SEPTIC PERITONITIS.\*

HORACE G. WETHERILL, M.D.

PROFESSOR OF GYNECOLOGY, DENVER COLLEGE OF MEDICINE.  
DENVER, COLO.

The acceptance of this title presupposes that you will permit me to assume that certain cases of septic peritonitis of appendiceal, intestinal and tubal origin may become inoperable, i. e., that the interests of the patient may be better served at times through the adoption of non-surgical measures. This position must be conceded by the radical appendicitis operators in the "operate as soon as the diagnosis is made" class, when they are pinned down to particularly grave cases, for they all meet some cases in which they are unwilling to operate.

Septic peritonitis usually has its origin in some local point of infection and the gravity of the symptoms depends upon the virulence of the infection and the area of peritoneum involved through the diffusion of the process: those measures that tend to limit the spread of the infection and favor its localization to a circumscribed area must favor the limitation of the disease and the recovery of the patient.

The oviducts, the vermiform appendix and the last loop of the ileum—the viscera from which such infections most often arise—are more or less favorably situated for the localization of the infection. Those who operate many times for such conditions have seen frequent instances of such limitations about the fimbriated ends of the oviducts and the vermiform appendix. Gynecologists see patients every day who present conditions of so-called pelvic cellulitis that we now know to be nothing more nor less than a circumscribed pelvic peritonitis, the result of infection from a leaking oviduct, which the conservative agencies of the animal economy are taking care of most beautifully through the formation of peritoneal adhesions and the deposit of plastic exudate about the danger point.

Infections from intestinal perforations, appendicitis and diseases of the oviducts are relatively dangerous in the order here given. Taking the total volume of all such cases the tubal infections are apt to be least malignant, those from the appendix much more so and those from intestinal perforations most malignant; moreover, the oviducts occupy the lowest point in the peritoneal cavity where walling off is most easily effected by nature, the appendix being less favorably situated and the intestines least favorably placed. Several years ago I heard the late Dr. John Ashhurst say, in a meeting of the

Philadelphia Obstetrical Society, that infections of the lower portion of the peritoneal cavity were better borne and better guarded than those of the upper part. While his statement was questioned then, I believe it would be accepted by surgeons quite generally at this time. To me it seems a very true statement, which my years of observation would confirm.

We must also take into account the volume of infecting material poured into the peritoneal cavity at one time and the relative activity and mobility of the viscus from which it comes, for this bears upon the diffusion of the poison as well as upon the ability of the peritoneum and omentum to cover and seal a leaking focus of infection; here again we find the tube most limited in its excursion, the appendix more free, and the intestine freest. As the relatively fixed organ permits of better protection from the peritoneum it would seem likely that the volume of infecting matter would be least from it, and greatest from the more freely movable ones. What we know of the clinical history of typhoid perforations and our findings at operations and autopsies subsequently would tend to confirm this view.

In its bearing upon treatment the foregoing pathologic résumé is of vital importance and must impress upon us the necessity for accurate diagnosis as to the source of our peritoneal infections and oblige us to consider carefully whether such cases as come under observation are safely operable cases at the time we see them and if not what the treatment should be until they may become safely operable.

As a surgeon and operator I am firmly convinced that early operations in all cases of this class are safer and wiser and more conservative of life than delay, that the operation adds little or nothing to the immediate danger in skilled hands and that the risks of the disease are vastly greater without operation than with it. This again is relatively most true of intestinal perforations, than of appendix infections, and least true of those of tubal origin. The time at which a particular case may be more safely regarded as inoperable can not be arbitrarily set down in hours or days, but must depend upon the differential diagnosis and the clinical signs. For example, the diagnosis being typhoid perforation, operation would be indicated in every case where the patient was not apparently about to die, because of the inevitably fatal result if he be not operated, the proportion of recoveries after operation fully justifying and demanding that he be given the one chance in about three for his life. If, however, the infection be of tubal or appendix origin and the peritonitis diffuse with a profound effect upon the heart and kidneys and other vital organs, it matters not how much or little time may have elapsed since the onset, that patient stands a better chance for his life without operation than with it and in my opinion

\* Read at the meeting of the Denver and Arapahoe County Medical Society, Feb. 25, 1902.

such a case should be pronounced inoperable. Occasionally, though very rarely, such cases recover after operation, but always in spite of it and not because of it. The many untimely operations on such cases, with the frightful mortality attending them, is largely responsible for the prevailing public opinion that such operations are usually fatal. The newspapers invariably announce death from the operation and not from the disease. Without operation such patients' chances are unquestionably better and if they must die the surgeon is relieved of the unpleasant odium of contributing to that end, and the rule of "the greatest good to the greatest number" is observed, inasmuch as patients presenting conditions favorable for operation will not be deterred by false notions of its gravity. Patients must learn that it is the disease that kills and not the operation and they can be so taught only by the performance of operations on operable cases and the treatment of inoperable cases by other and far better methods.

If we accept the pathology of these grave cases as I have outlined it and apply the facts to the treatment of diffuse peritonitis, some radical changes must be made in our views of the medical treatment as well as in our opinions of the saving virtues of the knife. If we admit that localizing and circumscribing an infected focus or even a considerable area of infected peritoneum is favored by the physiologic rest of the abdominal viscera and that freedom from motion and commotion in the peritoneal cavity predisposes to limitation rather than diffusion of the disease, we must adopt those means that lead to that end.

To Dr. A. J. Ochsner, Chicago, is due the credit of formulating and proving in practice the rational treatment of these terrible cases of diffuse peritonitis, cases that we must learn to pronounce inoperable as I have suggested. Ochsner's "Chairman's Address," delivered before the Section on Surgery and Anatomy at the 52d annual meeting of the American Medical Association and published in *THE JOURNAL A. M. A.* of June 22, 1901, states his position clearly and I beg leave to quote such passages as seem to lend force to this plea for its wider acceptance and adoption as the best method of treatment for such conditions. He says:

"It is a fact which has been demonstrated a great number of times that peristalsis does not occur unless food or cathartics are introduced into the stomach. \* \* \* \*

"Theoretically then, the disturbance which is to be feared to so great an extent is caused by the presence of food or cathartics in the stomach and its logical remedy would be to absolutely prevent the introduction of any form of food or cathartics into the stomach, and the removal by gastric lavage of any portion of food which may be retained in the stomach at the beginning of the attack.

"It may be necessary to perform gastric lavage twice or at most three times in order to entirely remove remnants of food which may have regurgitated into the stomach from the small intestines by reason of return peristalsis. \* \* \* \*

"It is true that a few surgeons have reported failures with this method, but an investigation of their treatment in each instance has shown that they disregarded one of three cardinal points in the treatment. They either gave just a little liquid food by mouth, or they gave some form of cathartics, or disturbed the rest of the intestines by giving large enemata, or they neglected removing the stomach contents by gastric lavage."

From his conclusions we may abstract the following as being most important:

1. Peristaltic motion of the small intestines is the chief means of carrying the infection from the perforated or gangren-

ous appendix to the other portions of the peritoneum, changing a circumscribed into a general peritonitis.

2. This can be prevented by prohibiting the use of every kind of food and cathartics by the mouth and by employing gastric lavage in every case in which there are remnants of food in the stomach or intestines above the ileo-cecal valve, as indicated by the presence of nausea and vomiting or meteorism.

3. The patient can be supported by the use of concentrated predigested food administered as an enema, not oftener than once in four hours and not in larger quantities than four ounces at a time.

6. In all cases of this class, gastric lavage should be practiced in order to prevent the absorption of decomposing material from the alimentary canal.

11. The treatment does not protect the patient against a subsequent attack.

12. It does not contra-indicate the removal of a diseased appendix before the septic material has extended beyond this organ.

13. It is indicated in all intra-abdominal conditions in which it is desirable to prevent the distribution of septic material by means of peristaltic motion.

14. The laity should be taught to stop feeding and giving cathartics to patients suffering from intra-abdominal diseases.

His results are conclusive; he reports:

"From Jan. 1, 1898, to May 1, 1901, I have operated upon 565 appendicitis cases which I have divided into three groups: 1. Those who enter the hospital suffering from diffused peritonitis. 2. Those who enter the hospital suffering from gangrenous or perforative appendicitis. 3. Those who enter the hospital suffering from recurrent appendicitis in the interval between attacks or at the beginning of a recurrent attack when the infectious material was still confined to the appendix. Of the first class I treated 18 cases with 10 deaths, 55.5 per cent. mortality; of the second class I operated on 179 cases with 9 deaths, 5 per cent. mortality; of the third class I operated on 368 cases with 1 death, one-third per cent. mortality; total 565 cases, with 20 deaths, 3.5 per cent. mortality. These statistics contain all patients who entered the hospital suffering from appendicitis, even those who died a few hours after admission from general peritonitis."

These statements are so clear, the conclusions so logical and the statistics so conclusive that it would be "painting the rose" to attempt to embellish them. I desire to add, however, that in the few cases in which I have had the opportunity to try Ochsner's plan of treatment the results have been most gratifying.

I wish to cite the case of a patient recently seen and so treated. This lady had a history of an old pelvic infection of tubal origin with a number of acute exacerbations in which she had been very ill, but never so ill as now. She was a patient of Dr. John C. Graham, with whom I saw her at St. Joseph's Hospital. Her temperature was 103.3 and pulse 130. The character of the pulse was bad. She was enormously distended, vomiting constantly a brownish fetid fluid with a distinct fecal odor, and the tenseness and tenderness of the whole abdominal wall was extreme. Her eyes were rolled up and her expression was that of one with but a few hours to live. I pronounced the case inoperable and urged the institution of the Ochsner treatment, starting in at once to wash the stomach and get rid of the fearful depressing effect of the toxemia incident to fecal regurgitation, for in my judgment this persistent nausea, depression and toxemia is in many instances quite sufficient of itself to determine the fate of the patient. The lavage had to be repeated. Absolutely nothing was permitted by mouth; rectal feeding was begun, and sharp hypodermic stimulation with strychnia and atropia was maintained. The results so far as

pulse and temperature were concerned were prompt and good, but the greatest improvement noticed was in the early disappearance of pain, vomiting and nausea, of tenseness, tenderness and distension over the abdomen and of the restlessness and anxiety so painfully evident in every movement and look. She recovered and is now about ready for an interval operation which offers her every possible prospect for health and longevity.

I must add just a few words condemning two drugs frequently prescribed in peritonitis: 1. I desire to endorse absolutely all Ochsner says about the harmful effect of salts in this disease and, judging others by myself, I take it that the habit of starting the treatment of these conditions with salts will be the hardest lesson the physician will have to unlearn, for that plan is part and parcel of the fixed routine of 95 physicians in 100. It will be even more difficult to impress the laity with the importance of leaving off the salts. 2. Opium, as frequently ordered, is also to be condemned. It does arrest peristalsis, to be sure, and some of you will say that it favors the very objects I seek; but unfortunately it does much more and in those respects its effects are so supremely injurious that the sum of its action is far from good. The point of this matter is, however, in the fact that, if the lavage and absolute fasting are maintained, both the salts and the opium are quite unnecessary, as the intestinal and stomach contents are removed and the peristalsis arrested by a better, simpler and far safer proceeding. This does not preclude the moderate use of morphin and codein hypodermically for the relief of pain, anxiety and restlessness in the early stages of the disease and its treatment, but if the lavage, fasting and avoidance of cathartics is strictly maintained the necessity for anodynes is soon past.

#### SUMMARY.

1. The treatment of septic peritonitis by surgical measures on the one hand or by rational medical measures on the other must be determined in each case first through a carefully-made differential diagnosis as to the source of the infection; second, through an estimate of the apparent virulence and diffusion of the infection, and third, through consideration of the elapsed time since the infecting material was injected into the cavity.

2. Infections from the intestines, vermiform appendix and oviduct are apt to be dangerous in the order given, because of the relatively greater mobility of the first and then the second and third, and of the greater relative distribution of their contents, which favors and promotes diffusion of infection and prevents plastic closure of the leaking viscus.

3. Physiologic rest of the intestines favors limitation of the area of peritoneal involvement and the saving of life, and is best attained by the maintenance of an empty bowel and the avoidance of cathartics; this means lavage, fasting and no salts.

If enemata are used for clearing the rectum, as may be required, they must be small in amount and injected with the utmost care from a low bag.

4. Cases of diffuse peritonitis with profound local and general symptoms must be regarded as being inoperable, inasmuch as the interests of the patient and the requirements of good surgery both demand that untimely surgical measures be not employed where better results may be had with simpler and safer ones.

5. Early operation, before diffusion has taken place, is safe and in most instances to be advised if the environment be favorable and an experienced surgeon at hand. Interval operations are certainly advisable after recovery from a diffuse peritonitis from any source.

## THE NEUROSES OF THE HEART.\*

HERMAN H. HOPPE, M.D.

CINCINNATI, OHIO.

In presenting for your consideration the subject of functional heart affection, I have a two-fold object in view: First, to illustrate by appropriate cases the undoubted forms of heart neurosis, and secondly, to call your attention to borderland conditions where we are frequently in a quandary as to whether the case would be classified as myocarditis or whether the cause lies in a functional disturbance of the nervous mechanism of the heart's action.

The subject of myocarditis and its clinical phenomena have lately been the subject of much discussion and the chronic form at least is of much interest to us, especially in our office practice where it often is important to know, and difficult to determine whether a given irregularity of the heart is of organic or functional origin. In the same way, when diseases of the muscular walls or of the valves do not enter into consideration at all, it is often impossible to determine whether the nervous derangement of the heart's rhythm is of an organic or functional character. If we omit from our consideration the subject of fevers and direct chemical poisons affecting the heart, we will render the subject more circumscribed and at the same time not detract from the interest in the matter. Various factors are essential to a normal condition of the heart's action. The muscles must be sound, the valves normal, the nervous mechanism perfect, and the heart must be in its usual position. When any one of these conditions is altered, the heart's action becomes changed, irregular, rapid, slow, tumultuous.

A nervous affection of the heart is caused by a faulty condition of the nervous system locally in the heart, the nerves leading to the heart, their center in the medulla, or by what is more frequently the case, by a derangement of the nervous system as a whole, such as we see in neurasthenia and hysteria.

The nervous ganglion system of the heart may be the central point of the disease, and according to Krehl, although this is still in doubt, future investigation may confirm this idea. The nervous condition of the heart is surrounded, as a rule, by all of the general and special signs and symptoms of neurasthenia and hysteria, but sometimes it is the only symptom. In order to understand the neuroses of the heart it is necessary to give a brief survey of its physiology. Twenty years ago the physiology of the heart was looked upon as a closed chapter; the Traube theory was universally satisfactory. He taught the two-fold action of the heart: *a*, the muscular motor system, *b*, the regulator system, viz., the accelerator influence of the sympathetic and the depressor influence of the vagus. To say that the theory is overthrown, at least in part, is to give you old news. Gaskell, Woolbridge and Tigerstead were the first to show that the experiments on which muscular theory was based were faulty, but it remained for His, Jr., Romberg and Krehl to put forward and apparently substantiate the theory of the autonomy of the heart. Engelman in a complete paper gave the theory its present standing. The myogenic theory of the heart's action is critically reviewed in an admirable paper by Leyden. It teaches that the heart is practically one muscle fiber with the power of automatic action. The ganglion cells and all the nerve fibers of the heart are sensory in char-

\* Read at the Cincinnati Academy of Medicine, Dec. 16, 1901.

acter. Carl Huber of Ann Arbor in an admirable paper which has the support of Waldeyer, tries to show that nerve fibers do enter and terminate in the nerve fibers of the heart by a small knob-like termination. But the consensus of opinion is against this theory. While the heart is rich in sensory fibers and ganglionic cells there are no motor fibers, no motor centers; the first decided blow to the neuron theory. The motor stimulus comes from the blood itself, perhaps from the chlorid of sodium alone. Kronecker, who had performed an experiment of pricking the center of the heart just below the aortic valves and thereby throwing the former into an irregular and tumultuous action, and finally causing it to stop altogether, seems to have found a motor center. But the most careful investigation, however, failed to reveal any accumulation of cells or nerves in this locality, and as long as ten years ago at the Berlin International Congress he explained the result by the irritation of the vasomotor nerves of the coronary artery. While the rhythm of the heart's action is automatic, this can be increased or diminished by influences, chemical, physical, or psychical in character, coming either through the sympathetic nerve or from the vagus.

We can divide the neuroses of the heart into three divisions: 1, neurasthenia cordis; 2, tachycardia; 3, bradycardia.

#### NEURASTHENIA CORDIS.

Under the head of neurasthenia of the heart various manifestations are seen. We have: *a*, typical neurasthenia of the heart, *b*, arrhythmia of the heart, *c*, pseudo angina pectoris, *d*, nervous bruit. Of these conditions, the neurasthenic heart is the best known and the most frequently encountered. This condition of the heart rarely occurs as the only sign of the neurasthenia. It is the local manifestation of a general condition. The neurasthenic condition being present, no matter what the cause, the local phenomena on the part of the heart are usually the product of the psychic influences. The most frequent condition which we see is the cardiac hypochondria, fear of heart disease. It is usually based upon the local precordial sensation produced by palpitation, irregularity or pain. Fear is the predominant psychic element of neurasthenia and the fear of heart disease is often combined with a marked disinclination to examination for fear of having apprehensions confirmed by the physician.

Palpitation, while frequent, is not an invariable sign of a neurasthenic heart. Its origin is often chemical or mechanical, due to displacement by a distended stomach. But when it is accompanied by a sense of fear and anxiety, I should say that it is at least associated with a general neurasthenic condition. Palpitation may occur without any cause whatever, often in the middle of sleep. It is associated with precordial distress, varying in degree from a slight pressure to pain so crucial and severe as to simulate angina pectoris. At the same time there is great mental distress, a pallid, moist countenance, and facial expression of great anxiety. At times the palpitation and precordial anguish is associated with a sense of constriction in the throat, a sense of strangulation which makes the patient jump from the bed, often from a deep sleep, into the middle of a room, uttering guttural noises or rushing to a window and throwing up the sash for air. These attacks come on suddenly and last from a few minutes to an hour or more. These paroxysms are only one phase of the neurasthenic heart. In some cases the heart is constantly twenty to thirty beats above the normal and

there is a sense of dissatisfaction with the breath taken, a constant effort to breathe deeper and a feeling that relief would be attained if a deeper inspiration could be made. This dyspnea may last for hours, days, or even weeks, the only relief being obtained by sleep.

The typical neurasthenic heart is weak, irritable and easily exhausted. When at rest the pulse is normal, but the slightest exercise, such as stepping up two or three steps to a platform, will raise the pulse rate from twenty to fifty beats per minute without any discomfort to the patient. In less than a minute after the patient has come to a halt, the pulse rate returns almost to normal. The same result is often produced by psychic influences, by coming into a physician's office and being examined. The sphygmographic tracing will show this weakness and irritability of the heart. The worst case of neurasthenia that ever came under my observation was a blacksmith, who worked daily at the forge for a whole year while he was under treatment. His pulse was so irritable, weak and rapid that the mere walking into the clinic in the presence of the students raised his pulse rate to 120 or more. This shows that there are exceptions to the rule. Just as irritable weakness, whether in the mental or physical sphere, is the characteristic of neurasthenia, so it is also of the neurasthenic heart. Krehl raises the question whether nervous affection can produce changes in the size of the heart. If so, how often and to what extent, and can it produce hypertrophy or dilatation? We might answer at once that when hypertrophy and dilatation are present there is an organic heart lesion, a diseased condition of the muscle itself. At present, however, there can be no certainty upon this point, principally because autopsies in nervous subjects are exceedingly rare. Krehl says that he has seen dilatation of the heart especially in masturbators and that with a cessation of the habit the dilatation has disappeared. He has also seen dilatation occur in ordinary neurasthenic paroxysms and disappear with the cessation of the attacks. Theoretically the explanation is very plausible. It is well known that an irritation of the vagus nerve has marked influence on the tone of the heart muscle. Why should not psychic influences have the same effect, the dilatation being the result of diminution of tone. Krehl is not so positive about the occurrence of hypertrophy; he thinks that he has seen it, but does not wish to place himself on record because of the difficulty of diagnosing small degrees of hypertrophy. Before the diagnosis of dilatation or hypertrophy can be made in neurosis of the heart, we must carefully exclude all organic lesions and must likewise bear in mind that we may have at the same time both an organic lesion and a neurosis. It is well to remember, however, that we may have as a result of simple neurosis of the heart undoubted dilatation and perhaps hypertrophy.

#### ARRHYTHMIA CORDIS.

In palpitation of the heart under the influence of psychic emotion, there is frequently not only an increase in the rhythm but there is a decided irregularity both in the rapidity of the action as well as in the occurrence of intermissions, and when the heart quiets down again we have a regular rhythmic pulse. In arrhythmia, on the other hand, we have a pulse that is irregular in rhythm, as well as intermittent, in the absence of all excitement, psychical or physical. Kronecker's experiment seemed to indicate that the cause of the irregularity in nervous patients may be due to some vasomotor disturbance of

the coronary circulation. Directly or indirectly, no matter how, the cerebrospinal system regulates the force and frequency of the heart, but the rhythm is the peculiar inherent automatic quality of the heart muscles and nerves. The most frequent cause of arrhythmia therefore is either a diseased condition of the coronary arteries or myocarditis. There can, however, be no doubt that we frequently find arrhythmia as a functional affection of the heart. Husley has shown that even in apparent health, variations not at all physiological occur, but marked arrhythmia to the point of intermitting is always pathological. The nervous heart may be intermittent; we may have a pulse bi-geminus, or trigeminus, or delirium cordis. All of the cases that I have seen have been neurasthenia with marked vasomotor disturbance. The great difficulty in neurasthenia lies in excluding myocarditis or organic nervous trouble. Certain cases had been diagnosed as Graves' disease but this was held to be untenable because of the irregularity of the heart, and of the fact that at times the heart's action was reduced to 80 beats or less per minute which never occurs in the former affection. The sphygmographic tracing of Graves' disease with a pulse rate of 130 will illustrate the difference in the two conditions. The rhythm of the heart is always perfect in Graves' disease. Myocarditis and disease of the coronary artery must be ruled out and this can only be done with great difficulty, especially in the start. We must rule out all acute diseases which might have caused myocarditis and arteriosclerosis.

Normal pulse.

Krehl lays much stress on allorhythmia, viz., an intermittence every fourth, sixth or eighth beat, recurring regularly. The intermittence of myocarditis occurs with great irregularity. In nervous arrhythmia there is a marked consciousness of the irregularity, which is usually absent in organic heart trouble. Arrhythmia of nervous origin sometimes disappears under excitement, while bodily exercise invariably increases the irregularity in myocarditis. Myocarditis is, as a rule, associated either with hypertrophy or dilatation, whereas in arrhythmia it is the exception. We must remember, however, that patients with myocarditis may have neurasthenia, and very often the same cause which produced the neurasthenia may also produce a myocarditis, e. g., influenza. In cases of this kind, time alone will clear up the doubt. Neurasthenic patients may have arteriosclerosis and this may complicate the diagnosis. Each and every symptom and sign should be carefully weighed in the balance and even then we may remain in doubt as to the exact nature of the arrhythmia. We can see the importance of a careful diagnosis by the bearing which it has on the treatment, for in neurasthenia an outdoor life is demanded and a gradually increasing amount of exercise, which may prove fatal to the case of sclerosis of the coronary artery or myocarditis.

#### NERVOUS ANGINA.

The nervous ganglia and nerves of the heart are, according to present teaching, purely sensory and therefore we may have in the heart, in addition to the other disturbances of sensation, distinct pain. This pain may

occur in paroxysm, simulating neuralgia, or it may be more or less constant with periodic exacerbations lasting from minutes to hours. This pain now and then occurs independently of any organic heart trouble and is known as nervous angina pectoris. There is no better authority than Romberg and he holds, in view of the many negative autopsies, that angina pectoris is always a neuralgia of the heart, that aortic stenosis and sclerosis of coronary arteries are merely contributing causes. There is even much dispute as to the seat of pain, the vagus, sympathetic, phrenic, intercostal nerves and the spinal cord having been looked upon as the seat of pain by undoubted authorities. I have seen one case of mild alcoholic brachial neuritis of the left arm which was associated with periodic attacks of precordial pain, radiating into the shoulders, which Oppenheim of Berlin saw with me and confirmed the diagnosis of pseudo angina pectoris. Prolonged rest and withdrawal of alcohol has up to the present time relieved the attacks. We are on very uncertain ground when we view the pathology of angina pectoris, and whether we hold the theory of coronary disease, of neuritis or neuralgia, we have undoubted authority to uphold us in our opinion. The most widely accepted view, however, is that true angina is caused by organic changes and most frequently by atheroma of the coronary artery. Angina pectoris, like tachycardia and bradycardia, is a symptom and not a disease. My object is not to treat of angina as such, but merely a pseudo-angina occurring in neurasthenia, which has a very close resemblance to the true form.

Normal pulse, case of brain exhaustion.

Whittaker says with truth that precordial pain, no matter how great its severity, does not constitute angina. We must have associated with it dyspnea, great anguish, mental anxiety and the fear of impending death. The cardiac crises of locomotor ataxia are purely neuralgic in character. We may have mild attacks of reflex angina arising from various disturbances of the liver, pelvic and gastro-intestinal canal. When angina is seen in alcoholic patients, I should hesitate to make the diagnosis of a purely functional neurosis. We may have a neuritis or even coronary arteriosclerosis. Tobacco, tea and coffee may produce attacks of pseudo-angina.

Since pain alone, its intensity, location and duration are the same for true angina as for the false we must look around for some differential point. True angina usually occurs in individuals who have other evidences of organic heart lesions, muscular or valvular. False angina occurs in individuals who are neurasthenic or hysterical. In the attack this point will not avail much, but outside the attack, in the interval, it matters a great deal.

Huchard gives the following points: First, every angina produced by an effort of any kind is true angina. Second, every angina which occurs spontaneously is false angina. Third, an angina which occurs in the night, though independent of effort, is a false angina. Nervous patients are not quiet during an attack. They walk up and down from chair to lounge, from lounge to bed, wringing their hands, lamenting and crying. The attack might be associated with other signs of neurasthenia.

thenia, as palpitation of the heart. Areas of anesthesia may be present. Pain may affect the whole left side. Neurasthenic cases are often associated with typical neurasthenic breathing. Most functional, reflex or neurotic anginas occur in young individuals; true angina in the old. Hysterical attacks of angina are often associated with typical hysterical mania, in which delusion of the senses of sight are very frequent, always being absent in true angina.

#### BRUIT AS A NEUROSIS.

Can a purely functional change in the rhythm of the heart produce a bruit? We see bruit frequently in the

Neurasthenia cordis.

various forms of anemia and in chorea and attribute it to the quality of the blood. But what ground have we for this assertion? If it be true, why do they not occur in all cases of anemia? Is it not just as probable that in these cases there is some disturbance of the mechanism of the heart, which produces the bruit or some anomaly in the muscular contraction which leads to a temporary faulty closure of the valves?

The following is a case of nervous bruit:

Mr. G., age 41, married, three children, has always been

Neurasthenia cordis.

healthy. No evidence of venereal disease, never sick, is applying for life insurance, was examined by Dr. Minor and myself at patient's office. On examination of the heart, a loud bruit was heard, even before the ear or the stethoscope was applied to the chest. It could be heard at least an inch from the chest. The heart was found normal in size and location. Its action was strong, somewhat rapid, pulse 100. Second sound slightly accentuated. The examination in other respects perfectly normal. Patient seemed only slightly excited. Urinalysis negative. Insurance refused. Second examination made in my office.

Neurasthenia cordis.

Heart perfectly normal in size and sound. No bruit. Patient attributed the disturbance at the examination twenty-four hours before to a dinner which he had attended on the night previous. On demand of applicant, the medical director of the insurance company came from New York and a joint examination was made after a lapse of ten days, the heart was again found normal, and the insurance granted in full amount.

It is difficult to explain, and we have not the time to go into details concerning the numerous theories that have been advanced, to explain the nervous derangement of the mechanism of the heart action.

Krehl, Martius and others look upon the result of

physiological experiments on animals and their application to the human heart with much distrust, not to say contempt. Very little reliance is placed by them upon the direct influence of the vagus and sympathetic nerves in the production of derangements of the heart's action. The whole subject is still in obscurity, but they seem to lay more weight upon the ganglionic system of the heart itself as the seat of all disturbances of action. Barker believes that the experimental and fetal researches of His, Jr., and Romberg have found a satisfactory anatomical basis of the physiology of the nerves of the heart and a starting point whence perhaps those puzzling clinical problems in connection with the cardiac neurosis may be advantageously approached. His, Jr., in his illustration of the ganglionic system of the heart, has likewise shown a wonderful blood supply of the ganglionic system. "Every ganglion is surrounded (as Whittaker so beautifully puts it) by a thick network

Neurasthenia cordis.

of small blood vessels and numerous branches penetrating into its interior. Thus the heart ganglia are in no sense degraded by being denied the office of presiding over the motion of the heart. They have the higher one of perceiving the first influence of failing nutrition or toxic impression."

The neuroses of the heart are, as a rule, found in those forms of neurasthenia in which the vasomotor disturbances are most common. Patients with cold, moist hands and feet, with bluish-red discoloration of the skin of the extremities, the tache spinal, the pallid, easily flushed faces, are the ones who most commonly have the cardiac disturbances. It is not difficult to understand that if the arteries and veins surrounding the cardiac plexus are in the same state of passive distension and sluggish activity, how readily all the neuroses of the

Neurasthenia cordis.

heart can be explained on the ground of a deficient nutrition, producing a changed activity of the cardiac ganglia.

The prognosis and treatment of neurosis of the heart are essentially the same as in neurasthenia, the discussion of which we will not be able to enter here.

#### TACHYCARDIA.

Nothnagel, Bouveret and Martius have made known the symptom complex, which we designate as essential tachycardia. Tachycardia is a symptom of various affections and not a disease; it occurs in a moderate degree in various organic heart affections; in any disease of the neck or mediastinum compressing the vagus; in central disease of the medulla and in poisonings. But it occurs also under circumstances in which it is the essential symptom of a paroxysmal attack, which has come to be recognized as a distinct affection occurring periodically in individuals otherwise well. In its true form

it has to be encountered but once to dispel any doubt as to its right to a separate classification. Real tachycardia occurs in individuals who are, to all intents and purposes, well between attacks. In others there has been found a nervous diathesis without there being present any marked hysteria or neurasthenia. The attack comes on suddenly, the individual feels a sensation of a sudden start or a darting pain in the chest, then a sense of fatigue, fear and anxiety. He goes to bed and lies perfectly quiet, but when the attack lasts a long time, there is more or less restlessness. Oppenheim, however, reports one case with exceedingly high pulse, the patient being able to go about his business and even walk for miles in an attack. The main symptom is the pulse and the pulse rate. I should say from the few cases that I have seen, that in genuine cases the pulse rate is never below 160, usually between 180 and 220 and Krehl says, as high as 300 per minute. The pulse is weak,

Case of obesity in young woman—no neurasthenia.

feeble and small. The heart's action is feeble and the impact against chest wall scarcely perceptible. Binswanger, however, reports a case with a pulse rate of 150, pulse hard and with strong impact against the chest wall. The heart sounds are clear, but so rapid as to be almost indistinguishable. There is no bruit. The presence or absence of dilatation of the heart is a much discussed question. I have seen one case with acute dilatation of the heart in which there were all the symptoms of the typical paroxysmal attack of tachycardia. In the other two cases reported below, I was unable to find any dilatation. Martius claims that dilatation is always present. Krehl says that it is not and that he has seen cases in which it was not present. There seems to be an agreement among authorities, however, that muscular weakness and loss of muscular tone is an

Pulse tracing one hour after admission, October 10.

essential condition of the attack and Krehl argues that if this is the case, theoretically at least, it would not be improper to imagine that an acute dilatation does occur and that while it may be hard to detect by percussion, it is very important to bear this in mind in making a prognosis as to the individual attack. The whole discussion, however, proves the first statement of this chapter, viz., tachycardia is a symptomatic manifestation of various conditions. The following three cases will illustrate the various conditions under which this may occur:

Miss L., age 29, single, dressmaker. Mother well. Father dead, was nervous. Has one brother who is a periodic drinker, who is nervous and hysterical. Patient has always been well, has worked hard and steadily at her occupation, has always been of a nervous temperament. Present trouble began two years ago. The attack always begins with palpitation of the heart, a feeling of oppression on the chest, difficulty of breathing, great anxiety, restlessness, and much physical exhaustion. First attacks lasted but a short time, never more than a half

hour, returning at intervals of a month. Each succeeding attack was longer and more severe. During the last year it was always necessary to administer a hypodermic injection of apomorphia, which would put an end to the attack. The last few attacks have lasted from three days to a week, during which period patient was confined to bed. On Dec. 5, 1899, I was called to see this patient. The attack has already been in existence for three weeks. It began suddenly like all the previous attacks with the following symptoms: Sudden feeling of oppression in cardiac region with sense of great palpitation. Intense apprehension, restlessness, pallor and dyspnea. Unable to sleep, unable to eat, vomits frequently. The violent palpitation has stopped but twice in three weeks and only for a few hours at a time. Examination: Patient is very pale, lips white, eyes sunken, with fear, anxiety and restlessness on the face. Complaints of violent action of heart and the feeling of suffocation. Action can be seen through chest wall; the apex beat is normal; no bruit can be detected. Pulse is over 200 per minute and usually so rapid that it is impossible to count it. No hyper-

Taken five seconds later than preceding chart.

trophy or dilatation. Radial pulse very thin and rapid, not compressible. No enlargement of the liver, no disturbance of the peripheral circulation. In previous attacks hypodermic injections of apomorphia gave prompt relief, but in the present attack none. In the sixth week the patient had a sudden attack of right side hemiplegia with difficulty of pronunciation. In the course of a week the hemiplegia improved, but there was no change whatever in the tachycardia. On the seventh day after the onset of hemiplegia, the patient suddenly died. It will be seen that this was an extraordinary case of tachycardia. The early attacks seemed to be essential, but judging from the fatal termination, preceded by the hemiplegia, there must have been a bulbar lesion which produced both the tachycardia and the sudden death. No autopsy could be obtained.

CASE 2.—Infant, age 7 months. Parents are both healthy. Has one older sister and brother, both well. Has been well since birth. Three days ago had an attack of gastro-intestinal

Taken October 14.

disturbance. Vomiting and diarrhea. Bottle fed. Temperature 100, pulse 100. I was called at midnight. Child collapsed suddenly. The face is pale, the lips somewhat blue and cyanosed. Is unconscious. Eyes half open, respiration 48. Radial pulse at times absent, at others, faintly felt, very small, thready, easily compressed. Heart normal in size. Heart's action varies from 180 to a frequency at which it can not be counted. The liver is markedly enlarged. The body generally pale and limp. Salt water injection made hypodermically. Very little improvement. Injection of 1/180 gr. strychn. sulph. gave prompt relief. Child recovered consciousness, pulse becomes stronger, 120 per minute. In 24 hours a similar attack. This, however, continues 12 hours, the pulse being constantly 180 and over per minute. Child unconscious, in state of collapse. Tendency to convulsions, with a scarcely detectable radial pulse. During the next two days has two similar attacks of short duration with recovery. The treatment in this case consisted of many neutral saline injections with three doses of strychnia strophanthus 3/4 gr. every 3

hours and ten doses of calomel gr. 1/20. Diagnosis, acute dilatation of heart.

CASE 3.—Mrs. K., age 58, married, four children, has had attacks of illness. For the past few months has been more nervous than usual. Has been under treatment for nervous indigestion. Complaints of violent heart's action and a sense of prostration, great mental distress and fear of death. Her face is somewhat flushed and has an anxious expression. No pain. Pulse weak, small, thready, 190 per minute. No bruit, no enlargement. Gave seidlitz powder and potassium bromid gr. 30 every 3 hours. In four hours no relief. While sitting at bedside, without any apparent cause, the pulse suddenly dropped from 180 to 78 beats per minute. This change took place instantly. Has had in all three attacks. The second attack lasted twelve hours, the third, three hours. In each attack the relief came spontaneously. Last attack five years ago, since which time patient has been comparatively well, with the exception of more or less neurasthenia.

It is important in the individual case to determine the cause of the attack. Myocarditis is very often the cause

Case A.—Arrhythmia—Irregular, violent, intermittent.

of tachycardia. In most cases there is some disease of the valves, coronary arteries or muscles, even dilatation or neuritis. While this is easily apparent on the autopsy table, it is very difficult to find during life. In essential tachycardia there is an absence of all indications of disease of the heart or nervous system in the intervals. In the attack we may find dilatation, but whether this is the cause or the effect is a matter of dispute. We must always remember the great difficulty that exists of diagnosing the slight deviation from the normal, either in the vessels or in the muscles of the heart. Martius says that all the attacks of tachycardia are the direct result of dilatation of the heart. Krehl takes a middle standpoint. The dilatation often follows the onset of the attack, may even be the cause, but is often absent. With Romberg he holds that the cause

When at perfect rest, pulse 72, irregular and intermittent.

is to be looked for either in a spasm or in a diseased condition of the coronary arteries, in a derangement of the nervous mechanism of the heart itself, and not of distant nervous system.

The diseased condition of the heart itself, viz., of the muscles, valves and arteries, can, at most, be only a predisposing cause, for, with the enormous frequency of the latter condition, tachycardia should be a very common instead of the rarest of cardiac affections.

Oppenheim has called attention to a group of symptoms which he says is due to irritation of the sympathetic nerves of the heart and of which tachycardia may be the most prominent symptom, viz., dilatation of the pupil on one side, wide separation of the eyeballs, pallor and reduction of the temperature of the face, with tachycardia. In making the differential diagnosis between essential tachycardia and that dependent upon disease, we must especially during the interval look for

all those signs and symptoms which may point to an organic lesion of the muscles of the heart, general arterial sclerosis, disease of the medulla oblongata or the occurrence of one of the acute infectious diseases which might have caused a neuritis of the vagus nerve. Whittaker says the irregularity of the pulse during the attack would be an indication of dilatation of the heart. Fraentzel says that tachycardia due to irritation of the sympathetic can be cut short by morphia and that produced by vagus affection by pressure on the vagus (Whittaker).

#### BRADYCARDIA.

This is exceedingly rare as a nervous affection. The bradus signifies slow—a slow heart. Bradycardia usually signifies a stenosis of the aortic valve, often complicated by myocarditis chronica or coronary artery sclerosis. There are at present two cases in the Cincinnati Hospital with pulses respectively of 32 and 36, both cases being of organic nature. In the clinical records

In paroxysms of palpitation, pulse goes as high as 140 per minute.

of the Cincinnati Hospital I have been able to find one case in the past ten years, also organic in character. A slow pulse of 60 or 64 is very rare, however. One of my patients who has been a neurasthenic for the past 20 years has a pulse habitually of 54 or 56. This patient has very marked attacks of palpitation and all the other manifestations of neurasthenia cordis, but only in paroxysmal attacks which occur at intervals of months, induced usually without cause, but at times by indigestion. The attack is invariably attended and followed by the fear of having organic heart disease, which is invariably dispelled by a formal examination and a positive statement to the contrary. Still I would not like to classify this case as one of bradycardia.

I have seen another case of slow heart in a neurasthenic with periods of intermittent pulse, rate 60, in

These last four tracings were taken at one sitting.

which no cause but a psychic one, the fear of heart disease, could be found. The intermittent pulse was present for a period of months. Tobacco was alleged as a cause, but its withdrawal or its continued use seemed to make no difference in the attack. We can also rule out myocarditis in this particular case. I have known him for seven years and he is still in good health with no evidence of organic lesion. I should look upon these two cases as unusual, because they occur in neurasthenia. Another patient now under my care for insomnia, fear of insanity and general nervous and physical exhaustion had a pulse of 54 for 10 days. At present it is normal.

Physiological bradycardia is seen often. Napoleon is said to have had a pulse of 40. Ruhlin, the pugilist, is said to have a pulse of 44, even after exercise. Bradycardia as a sign of organic heart disease or as a symptom of organic brain or cervical myelitis or injuries to the chord in the cervical region is not infre-

quent, but as a neurosis pure and simple it is exceedingly rare. Bradycardia is most frequently encountered in stenosis of the coronary artery. The bradycardia seen after the acute infectious diseases are probably due to mild myocarditis, while that always seen in conjunction with jaundice is probably due to the direct action of the circulating bile on the heart or on the nerve centers.

Reflex bradycardia is usually seen in gastro-intestinal disturbances and this is due to disturbance of the splanchnic circulation, throwing increased pressure and work on the heart. Attacks of bradycardia are described by nervous patients very frequently. These attacks are paroxysmal, not like tachycardia, but have more the character of palpitation or they may be associated with palpitation. The general signs are those of precordial pressure, anxiety, a sense of constriction, fear of suffocation and a subjective feeling as if the heart were beating very slowly and forcibly, combined with the fear of

Case of exophthalmic goiter, pulse 130, heart's action rapid, rhythm and strength normal.

its stopping altogether. The extremities become cold, the face pallid and covered with perspiration. In other cases there is distress in the stomach, nausea, retching, vomiting and subsequent collapse (Whittaker). The attack comes on suddenly and ceases suddenly. In milder cases there is simply abdominal distress, tenesmus, at times diarrhea. Sometimes bradycardia is associated with pain, which simulates very closely that of angina pectoris. Bradycardia is at times complicated with epileptiform convulsions. Whittaker says that these convulsions may be due to brain anemia, but he believes that the bradycardia and the epilepsy in the given case are both due to the same arrangement of the central nervous system. Before we can make the diagnosis of nervous bradycardia we must rule out all or-

Case of irritable, neurotic heart: pulse at rest, 80; under excitement, 130. Pulse regular and rhythmic, but action weak. Strong, muscular man.

ganic disease of brain, cord, heart or distant organs. The prognosis of functional bradycardia upon a neurasthenic brain is not unfavorable.

The treatment of bradycardia of a functional character is identical with that of neurasthenia. In the paroxysm we can use the various sedatives, bromids, asafetida and valerian.

## ACUTE CONGESTIVE OR INFLAMMATORY GLAUCOMA.\*

CHARLES J. KIPP, M.D.

NEWARK, N. J.

Not long ago I was asked by a medical practitioner to see an old lady who had for some days been suffering from a bilious attack, and who, since the day before, was nearly blind. He thought, as the eye seemed to be pushed somewhat out of the socket and she was blind, that she had probably during the retching and vomiting broken blood vessels in the orbit and in the eye. I saw the patient soon after and learned that she had been vomiting almost incessantly for two days, that she had great pain in the left side of the head, in the teeth and the eye. She was greatly prostrated. On examining her eye, I found that she could scarcely see the flame of a candle held within a few feet of her eye. The eye was very sensitive to light. The eyelids were somewhat swollen. The eyeball was slightly protruded from the orbit. The ocular conjunctiva was greatly ingested and swollen and a fold of it hung out of the palpebral fissure. The cornea was very cloudy and its epithelium was rough; touched with a piece of paper it seemed less sensitive than normal. The anterior chamber was very shallow, the iris swollen, and the pupil nearly double the size of that of the other non-affected eye. The opacity of the cornea prevented an examination of the fundus. A faint red reflex was all that could be seen. The eyeball was very hard, much harder than the other one. I made the diagnosis of acute inflammatory glaucoma, and advised an iridectomy as soon as possible. I instilled a few drops of the solution of the salicylate of eserine, which had, however, but little effect. The iridectomy was done under ether anesthesia a few hours later; the pain and the vomiting did not return after she came out of the ether, the wound healed rapidly, and three weeks after the operation the vision was restored to the former acuity.

I have related this case here, because cases of this group of acute glaucoma are most likely to fall in the hands of the family physician. The incessant vomiting, the violent pain in the head and the prostration are usually attributed by the patients to some stomach trouble, a bilious attack, or some disease of the head. The loss of vision, if noticed at all, and the redness and painfulness of the eye are frequently looked upon as a cold in the eye and not part of the general illness, and the family physician is sent for. I have seen a number of such cases, and I must admit that in some of these cases the physician took the same view of the eye trouble as the patient, and discovered his mistake only when the eye was totally blind and beyond help. In the majority of cases of acute glaucoma the onset is not as severe as in the case related. The pain is not as violent, vomiting may be entirely absent, and the headache may be much less severe. The outbreak is, moreover, in many cases preceded by attacks of cloudiness of vision lasting from a few minutes to several hours. The attacks come on at irregular intervals and are usually thought to be brought on by a sleepless night, an attack of indigestion, overuse of eyes in near work or some emotional disturbance. A restful night often restores the eye to its previous good condition, at least in the estimation of the patient, but a careful examination often shows some impairment of central vision, or slight contraction of visual field after the attack. Dur-

\* Read before the Newark, N. J., Medical and Surgical Society, December, 1901.

ing the fogginess of vision in these attacks the patient, looking at the flame of a candle or a lamp, sometimes sees a colored ring around it. This ring is separated from the flame by a dark zone, its outer limit is red and its inner green-blue. It is regarded as an interference phenomenon caused by the cloudy media of the eye. The attacks here described constitute, according to some authors, a premonitory stage of the glaucoma, but I believe that it would be safer to regard them as the first stage of inflammatory glaucoma and to perform an iridectomy at once.

The diagnosis is, as a rule, not difficult in uncomplicated cases. The increased intra-ocular tension and the dilated immovable pupil are pathognomonic of this disease. To ascertain the tension the patient is directed to look downwards without closing the eye; the surgeon then places the tips of his two index fingers close together on the upper eyelid and makes slight alternate pressure on the globe some distance behind the cornea. If the eye is in a normal condition, the tension of this should be ascertained first and then that of the other compared with it. If the patient's other eye is not in a normal condition, comparison may be made with the tension of a normal eye of another person of about the same age as the patient. It requires, however, considerable experience to recognize moderate variations in tension even in eyes that are not inflamed, and the difficulty is much greater if there is swelling of the lids and edema of the ocular conjunctiva.

Dilatation and immobility of pupil is found in no other acute inflammatory eye disease, and even here it is not developed till other symptoms of inflammation have been present for some time. The pupil is not always round; very often it is of oval form, the long axis being vertical. It does not contract when exposed to the light, or the movement is at least very sluggish. If the eye has previously been affected by an iritis and some of the adhesions between the pupillary margin of the iris and the anterior capsule remain, the pupil may be of very irregular form. Unless the case has been under observation from its very beginning, careful inquiry should be made as to whether a solution of atropin, scopolamin or some other mydriatic has not been instilled in the eye, as those would also produce such dilatation. The cause of the dilatation of the pupil is, according to some writers, due to anemia of the iris caused by the compression of the base of the iris between the congested ciliary processes and the cornea. If the pressure is long continued, paralysis and atrophy of the sphincter muscle of the iris result from the compression of the nerves of the iris.

The insensibility of the cornea present in severe cases is due to compression of the nerves of the cornea by the increased intra-ocular tension. Shallowness of the anterior chamber is rarely a conspicuous symptom and requires oblique illumination for its detection. In some cases, however, the iris seems almost pressed against the cornea. The other symptoms, as the swelling and puffiness of the eyelids, the injection and edema of the scleral conjunctiva, the opacity of the cornea, are seen also in other acute inflammatory affections of the eye. In severe cases of irido-choroiditis the cornea has often the same cloudiness "like glass breathed upon," or has in it numerous short opaque lines running in various directions and often at right angles to each other. There is, however, this difference between this cloudiness of the cornea of glaucoma and that of other diseases, namely, in glaucoma the haziness will at times develop and again disappear in a short time, while in the other affec-

tions it always lasts a long time. I have more than once seen this opacity disappear in glaucoma cases in a few hours after the instillation of a few drops of eserin. The cloudiness is evidently the result of a rapid increase in the intra-ocular tension in these cases. Sometimes the corneal epithelium is found to be rough in acute glaucoma and some writers have seen small vesicles on the surface of the cornea in such cases. Acute inflammatory glaucoma is rarely seen in persons under 35 years of age, in most cases the patients are over 50 years old. Women seem to be slightly more frequently attacked by this disease than men.

The predisposing causes of acute glaucoma include gout, rheumatism, syphilis, congenital imperfection of the eye, senile changes and heredity. As exciting causes are regarded: depressing emotions, sleeplessness, deterioration of the general health, great fatigue, and instillation of a solution of atropin or other mydriatic.

Whilst increased intra-ocular pressure has been universally recognized as the essential of glaucoma since MacKenzie's time, there still prevails considerable diversity of opinion as to the causes of this increase of the intra-ocular tension. By some writers it is held that it is due simply to a hypersecretion of the vitreous fluid caused by an irritation of the nerves of the ciliary body, which latter is generally supposed to supply this fluid. Others hold that it is the result of an exudation of serous fluid, from the inflamed ciliary process and the choroid. The opponents of these theories claim that hypersecretion and exudation alone are incapable of producing the increase of tension, as experiments on normal living eyes show that an increase in the volume of fluid and therefore an increase in the tension of the eye produced by the injection of a small quantity of fluid in the eye, is speedily removed by the absorption of the fluid and a return to the normal tension. The theory which seems to find most acceptance at present is that the aqueous humor, which under normal conditions is supposed to escape by filtering through the angle of the anterior chamber, is prevented from doing so by the closure or blocking of this outlet. This is the retention theory. It is said that obstruction of the angle of the anterior chamber, also called filtration angle and spaces of Fontana, is commonly found in eyes blinded by glaucoma, and if not entirely closed it shows at least signs of compression. Priestly Smith holds that primary glaucoma usually depends on some vascular disturbance which congests the choroid, ciliary body and iris, or upon a faulty relation of the lens to the parts around it, or upon both. He holds that "in elderly people the lens is relatively large and that the relations of the lens in small eyes are such as to predispose to compression of the filtration angle, especially during dilatation of the pupil. An obstruction in the region of the hyaloid and the circumferential space, which checks the escape of surplus fluid from the vitreous and leads to an advance of the lens, appears to be present in many cases. Through one or other of these causes, or several in combination, the ciliary processes are pressed against the iris and the filtration angle is narrowed or closed. The escape of the fluid is retarded and the intra-ocular pressure rises. The increasing pressure hinders the flow of blood through the choroidal veins and augments the swelling of the ciliary processes, this in its turn increases the compression of the filtration angle. We then see that the condition perpetuates and intensifies itself in a vicious circle. A typical acute glaucoma is an inflammatory disease in the same sense that a strangulated hernia is so, but not otherwise; it exhibits an acute ob-

struction of the circulation which can be cut short by the removal of the pressure but in no other way."

Others are of the opinion that the swelling of the ciliary processes from venous stasis or from inflammation causes their points to press against the posterior surface of the iris. Thus the root of the iris is pushed forward so far that it lies against the anterior part of the sclerotic and the margin of the cornea and later becomes adherent to it.

Laqueur thinks that in glaucoma we may have both hypersecretion and retention. He looks upon the ciliary body as a kind of gland, the nerves of which, under strong irritation, starting centrally, cause hypersecretion. This causes an increase of tension in the vitreous body chamber and in the posterior chamber. As a sequence, the iris is immediately pushed forward, and as a consequence of the increase of the tension in the anterior chamber which now also takes place, the aqueous humor flows from the filtration angle till the tension is equal in both chambers. The anterior chamber is now shallower, and the periphery of the iris is pressed against the margin of the cornea. The filtration angle is now narrowed, perhaps obliterated, and the further escape of the aqueous humor is made more difficult or is entirely prevented. While the hypersecretion continues, the signs of increased pressure become more manifest and the well-known picture of acute glaucoma appears. The true cause of glaucoma, he thinks, is of an extra-ocular nature, but predisposing conditions must be present in the eye, and as such he regards racial peculiarities, rigidity of the sclerotic and the hypermetropic form. The inflammatory symptoms and the anatomical changes he regards as secondary. A decrease of the venous outflow he does not regard as probable, as the veins of the eye contain but few muscular fibers and also because signs of stasis may be entirely absent in the mild premonitory attack. With regard to the nerves which regulate the secretion of the ciliary processes, he holds, we only know that they are not supplied by the fifth pair.

Stilling also believes that emotional disturbances increase the secretion of the intra-ocular fluid. In young people this is easily compensated, but in old people it meets with more or less difficulty because the compensatory channels for the outflow, the lymph spaces of the sclerotic and of the disc of the optic nerve, have been made impermeable through senile changes, namely, sclerosis. We must therefore look upon genuine glaucoma, he says, as a hypersecretion in senile eyes, that is, in eyes with contracted outlets. The augmentation of intra-ocular fluid is of itself a physiological process, only the eyes in which it takes place are no longer normal; in other words, they are no longer young. Something takes place here similar to senile hypertrophy of the prostate gland. If a youthful individual, from any cause, for instance much drinking, secretes an unusual quantity of urine, this hypersecretion does not cause the least disturbance because the excess can flow off without difficulty, but in an old man with contraction of the neck of the bladder, retention and its consequences follow. He denies that obliteration of the filtration angle is the cause of the increased intra-ocular tension, and regards it, if present, as the result of such increase. This view is held by many other writers.

Of the pathological anatomy of acute inflammatory glaucoma we know but little, as few eyes have been examined anatomically in the earlier stage of the disease. Closure of the filtration angle, due to adhesion of the iris to the periphery of the cornea, was found in most cases in which glaucoma had existed for some time.

In more recent cases the angle was found not unfrequently open and in some of these cases there were absent also other causes of retention, such as sclerosis of the trabeculae, emboli of pigment and obliteration of the sinus venosus sclerae. In the eye of a woman 54 years of age, removed on the eighth day after the beginning of an acute inflammatory glaucoma, Birnbacher found that the filtration angle was closed in several places; this was due to the union of the surface of the iris with the ligamentum pectinatum, which union did not, however, extend to the root of the iris. The anterior surface of the iris was inflamed. There was a diffuse serous choroiditis, as evidenced by an exudation, rich in albumin in all parts of the choroid. A pathological proliferation of the endothelium of the two upper vortex veins was found, an edematous swelling of the optic papilla and a slight depression of the lamina cribrosa. He and Czermack have found in chronic cases, well-marked signs of a past or present inflammation of the sclerotic and of the uvea, especially along the vortex veins and the scleral emissaries. These changes are designated chronic hyperplastic periphlebitis with consecutive endophlebitis, and their presence, they think, causes extensive disturbance of the circulation. This remains latent as long as there is compensation, but as soon as the compensation ceases to be complete, this becomes manifest as increased intra-ocular tension, and produces the picture of glaucoma. Others have found similar changes in the walls of the arteries and veins of the retina and optic nerve.

#### TREATMENT.

We have seen that mydriatics will sometimes bring on an attack of acute glaucoma, and will aggravate the disease if already present. It is therefore a good rule not to use atropin or other mydriatic for an inflammation of the eye, especially in elderly people, till you have assured yourself that the pupil is smaller than normally, and that the tension of the eye is not increased. As soon as you are convinced that acute glaucoma is present, eserine, either the sulphate or the salicylate, in one-quarter to one-half per cent. solution, should be instilled, and the instillation should be repeated at short intervals, till an iridectomy can be made. Eserine will occasionally increase the pain in the head by producing a superorbital neuralgia. If it does this, a 4 per cent. solution of pilocarpin must be substituted, although pilocarpin is by no means as efficient as eserine in contracting the pupil in acute cases. It is best not to prescribe either drug in a large quantity or to permit a renewal of the prescription, as I have seen a number of cases in which these drugs produced so much relief from the pain that the patient declined to have an iridectomy made, and did not consult me for subsequent attacks, but used the drugs in the belief that they were curing the disease, while in reality he was slowly becoming blind. Cocain in 3 or 4 per cent. solution may be used in connection with the myotics. It seems to relieve the pain and to do no harm. In addition to myotics and cocain, morphin should be given hypodermically in sufficient doses to produce sleep. In some cases the salicylate of sodium is also very useful in subduing this pain. Under medical treatment alone, as I have already said, an acute attack will sometimes pass over without leaving great impairment of vision, and in such cases the operation of iridectomy may be delayed for a while. But if no marked improvement is produced within a short time by these remedies, it will be necessary to make an iridectomy without delay, even

if great prostration from other causes would seem to prohibit it.

Iridectomy is the remedy par excellence in this disease; it has stood the test of time and the world owes a great debt of gratitude to the late Von Graefe for its discovery. While it is true that we may have good results from the operation if it is made within two weeks after the outbreak of the attack, there is no doubt that the result will be better the earlier it is made. Like other operations, iridectomy has its limitations; it can not restore the loss of sight and the contraction of the visual field that are due to anatomical changes in the optic nerve, produced by long continued or very rapidly increased intra-ocular pressure; all it can do is to remove the turbidity of the media and ischemia of the retina due to increased pressure. If both eyes are suffering from acute congestive glaucoma at the time the patient is first seen, the question arises: Shall we operate on both eyes at the same time or shall we operate on but one, and if only one, which, the better or the worse? Most operators of experience regard it as bad practice to operate on both eyes at the same time, as it is well known that the predisposition to choriorretinal hemorrhage and to malignant glaucoma, exists almost always in both eyes. The safest plan undoubtedly is to operate first on the worst eye and if all goes well to operate on the other some days later. I have been obliged to operate on both eyes at the same time and have had no reason to regret doing this. My practice has been in cases in which both eyes were affected, when first seen, to instill a 0.5 per cent. solution of eserine several times and if a marked contraction of the pupil follows in one eye, but not in the other, to operate first on the one least affected by the eserine and on the other several days later. If the eserine has no effect on either eye, I have administered a general anesthetic and operated on both eyes at the same time.

It is a well-known fact that soon after an iridectomy in acute inflammatory glaucoma the other eye which was apparently sound when the first was operated on, becomes attacked by the same disease. This occurred in several of my cases in former years. In most of these the symptoms subsided under eserine for a time. In the cases which did not yield to this drug, I operated at once. For several years I have instilled eserine in the sound eye before the operation and during this time the patient was in bed, and since then I have had no case in which the good eye was attacked while the patient was under treatment. Although months and even years may elapse before the second eye is attacked, it very seldom escapes entirely. With this fact in view, together with the fact that it is much easier to make a satisfactory iridectomy on a sound eye than on one that has glaucoma, some of the German surgeons do not hesitate to advise an iridectomy on the still healthy eye, before even the premonitory stage is present. Commenting on this fact, Czermack<sup>1</sup> says: "One can also advocate a prophylactic iridectomy on an eye that shows only signs of a disposition to glaucoma, that is, if it has a markedly shallow anterior chamber and the other is suffering or has already suffered from glaucoma." More recently De Schweinitz has pleaded for a prophylactic iridectomy under the same circumstances, in a paper which he read before the American Ophthalmological Society in 1901. Bearing in mind the accidents that have happened to me and others in eye operations, I should hesitate to urge upon my patients a

prophylactic iridectomy unless they were obliged to go to some remote region where competent help could not be had.

#### METHOD OF OPERATING.

To make a large and clean iridectomy in this disease, with much chemosis, a very shallow anterior chamber and a widely dilated pupil, is one of the most difficult tasks the ophthalmic surgeon is called upon to do. If great chemosis is present and the pupil can be contracted by eserine it will sometimes be to the best interest of the patient to delay the operation till the chemosis has somewhat subsided. A general anesthetic will be required in many of the acute and chronic inflammatory cases, though the subconjunctival injection of cocaine and eucaine are said to produce sufficient insensibility to permit of an accurate operation. Instillation of cocaine or holocaine, even if combined with solution of the extract of suprarenal glands, rarely reduces the sensibility sufficiently in these cases.

Unless the iris is more disorganized here than elsewhere the iridectomy should be made upward, so that the coloboma lies under the upper lid. I nearly always use a narrow cataract knife for the incision, enter the sclera about one mm. from the clear corneal margin and make the counter-puncture at a corresponding point. The section should have a length of 8 mm. In cutting out, the edge of the knife is turned slightly forward, but should come out in the sclera and make the conjunctival flap as narrow as possible. In cases of very narrow shallow anterior chamber it is not always practical to make an incision of this length and one must be satisfied with a smaller one. The iris is seized at about the middle of its width, drawn straight out and cut close to the lips of the wound by two or three successive strokes of the scissors, first close to one end of the incision, then at the middle, and last at the other end. If the sphincter corners do not return to their natural position, a blunt probe should be carefully introduced into the anterior chamber to disengage the incarcerated iris from the angles of the wound. Rubbing the adjacent cornea will only rarely accomplish this. Some surgeons prefer to make the incision with a broad lance-shaped knife and to tear the iris from its root. I have tried both but have given them up.

Of the accidents during the performance of iridectomy, wounding of the iris and lens capsules are most frequent. If the point of the knife becomes engaged in the tissue of the iris slight lateral and forward movements will usually disengage it. If not successful in this, the knife must be withdrawn and the wound be enlarged with a fine pair of curved scissors. The anterior capsule may be wounded by the point of the knife, by pressure of the back of the knife through the iris intervening, by the iris forceps during manipulation to reduce the incarcerated iris in the angles of the wound, by the sudden advance of the lens through the sudden reduction of pressure. The development of cataract in a glaucomatous eye is fraught with the gravest consequences and extraction of the lens is usually necessary. Hemorrhage in the anterior chamber is of frequent occurrence after iridectomy and does not interfere with the healing process. Prolapse of vitreous is not often seen during the operation and its occurrence does not seem to do much harm.

The after-treatment pursued by me in the last few years has been very simple. I keep the patient in bed till the wound is closed. I place an aluminum shield over the eye; cleanse the eye daily with sterilized water

1. Augenärztliche Operationen, Part 7, p. 762, 1898.

and instill a drop of the atropin solution after each dressing. I leave the other eye open and instill one drop of a one-quarter per cent. eserine solution in it once daily. This plan of treatment is much more comfortable to the patient than the bandaging of both eyes and the healing of the wound seems to progress as speedily as under the bandage.

## CASE OF CESAREAN SECTION UNDER SPINAL ANESTHESIA.

S. R. HOPKINS, M.D.  
SPRINGFIELD, ILL.

A report of the following successful case is not presented because of anything particularly peculiar in the operation itself, but mainly in an attempt to show what appears to the author the superiority of spinal anesthesia over ether or chloroform in cases of Cesarean section, because of the relaxed condition of the uterine muscles likely to obtain with the patient anesthetized by either of the two latter methods.

The patient, a primipara, 28 years old, of small stature, suffered in early childhood an attack of poliomyelitis anterior acuta, as a result of which the right side of the body failed to keep pace in a matter of growth and development with the left. The right arm is  $4\frac{1}{2}$  inches shorter than the left, and the right half of the pelvis is correspondingly small, which fact, together with the markedly kyphotic condition of the lumbo-sacral spine, was largely responsible for the necessity of Cesarean operation. The diagonal conjugate measures 9 cm. The external conjugate (Baudelocque's diameter) measures 16 cm.

She had been pregnant twice before, but aborted each time at about the second month. During the present pregnancy the child had never entered the true pelvis, but rode above the brim. Deeming Cesarean operation the only way possible to bring the child living into the world, the patient, on Dec. 21, 1901, was removed to the hospital two days before full term in order to have her prepared for the operation, which preparation was done as for an ordinary celiotomy, the vagina also being rendered as nearly aseptic as possible. After labor had been in progress sufficiently long to insure good uterine contractions and dilatation of the os, there was injected into the spinal canal one-third grain of cocaine hydrochlorate; the spinal fluid was used as a solving medium according to the method of Guinard of Paris, who has reported 70 cases anesthetized in this way, with none of the usual distressing post-anesthetic phenomena.

After the injection the patient was immediately transferred to the operating table, the abdomen and vagina again subjected to mechanical and chemical disinfection, by which time the entire body below the neck was anesthetic. A median incision, extending from  $2\frac{1}{4}$  inches above the os pubis to  $2\frac{1}{2}$  inches above the umbilicus, was made through the abdominal wall and the pregnant uterus eventrated through the incision, the upper part of which was closed by Volsella forceps under the fundus, thus preventing exposure of the intestines. The uterus was at once covered by two large pads wrung out of saline solution, and in the median line between these pads an incision was made through the uterine wall, exposing the placenta attached in front. With the index finger of both hands, the placenta was torn through, the child extracted, and after its respiration was established the cord clamped and cut and placenta and membranes

peeled out with the hand. During the incision of the uterus and extraction of child and membranes, the pads were several times changed for fresh hot ones and the interior of the uterus was, after being emptied, douched with hot water.

Uterine contraction was prompt, vigorous and perfect, and hemorrhage less than usual when the child is born *per vias naturales*.

Interrupted sutures of heavy chromicized catgut were used to close the uterine incision, and a continuous Lembert stitch of silk to close the uterine peritoneum. By previous request of patient the tubes were doubly ligated with heavy silk in order to render her sterile. The abdominal incision was closed in the usual manner, using silk for the peritoneum, and silkworm gut for the musculature. A dry dressing was placed over all, a vaginal examination made to insure good uterine drainage, a pint of saline solution used subcutaneously below the clavicles and the patient returned to bed. The child, a female weighing  $4\frac{1}{2}$  pounds, was allowed to nurse at the end of 24 hours.

The usual annoying post-anesthetic phenomena of headache and vomiting were absent in this case, probably attributable to the use of spinal fluid as a solving medium for the cocaine, thus avoiding the introduction into the spinal canal of a foreign substance (water), and also possibly because the intraspinal pressure was not increased by the injection of fluids, other than normally belonged there. In one other of my cases of spinal anesthesia wherein the cerebrospinal fluid was used to dissolve the cocaine no headache nor vomiting followed the procedure.

In the case above referred to the operation required forty minutes for its completion, and anesthesia was profound during that period though tactile sense was not lost. Save for a phlebitis which developed in the left leg at the third week to disappear in five days under elevation and cold application, the mother made an uninterrupted recovery and left the hospital with her child at the end of five weeks.

The only recorded case of Cesarean section done under spinal anesthesia that I was able to find was performed by Doleris of Paris, who speaks in glowing terms of its usefulness in these cases because of the prompt and vigorous uterine contraction.

Where Cesarean section is done for placenta previa the grave danger of the failure of the uterus to contract because of the woman having suffered the loss of much blood previously is well known to all the obstetricians.

In the case of Dr. W. J. Gillette of Toledo, Ohio, wherein a Cesarean section was performed for placenta previa, after ten minutes of manipulation the uterus refused to contract, and required extirpation. It is not impossible that spinal anesthesia would have obviated this.

The well-known and powerful oxytocic properties of cocaine hydrochlorate, particularly when given intraspinally, must surely recommend its use in cases wherein a failure of uterine contraction is at all possible.

Not much has been written upon the subject of intraspinal anesthesia in obstetrics. The first, and perhaps the most extensive is a monograph by Malartic, entitled, "Les injections rachidiennes de cocaine in obstetrique," Paris, 1901.

Apparently a large field is open in this direction, and cocaine, subdurally for cases of uterine inertia with maternal exhaustion and in the previously mentioned class of cases, surely merits a fair trial.

## A CASE OF BLASTOMYCETIC DERMATITIS(?)

JOHN GLENDON SHELTON, M.D.

Surgeon-in-Chief to the Montrose Hospital; Consulting Surgeon to the Telluride Hospital.

MONTROSE, COLO.

A Polish woman, 32 years of age, came under my care in May, 1901, suffering from a disease involving the face and causing blindness of the right eye, destruction of the nose and marked eversion of the lips. Her family history was negative. She was born in Poland and came to New York when she was 10 years old and was never sick, excepting the present illness. Venereal diseases were denied.

The history of the present complaint is as follows: About one year ago the patient noticed a pinhead-sized, firm, slightly tender swelling near the right angle of the lower jaw. The swelling was located in the skin and was freely movable. In a few days it developed into an abscess which ruptured, leaving a small ulcer. From this beginning the process extended, usually by induration and swelling followed by pus formation, crustation and, in some places, by resolution and cicatrization. In a few months the regions of the neck, mouth and nose were involved. Later the right side of the face, right eye and right ear became affected. The process still progressed, and when I first saw her the disease had advanced to the extent shown in the photograph—involving the neck, face, ears, forehead and, in places, the scalp.

The symptoms complained of were local pain, tenderness and itching; difficulty in eating and speaking, due to involvement of the lips; uncontrollable escape of salivary secretion from the mouth; epiphoria, and, during the last three weeks, progressive dimness of vision of the right eye. No other symptoms were complained of. Her general health seemed good. She felt strong, was able to work and had lost no weight. Examination of the heart, lungs, abdomen, extremities, nervous system and genitals revealed nothing abnormal. The lymphatic system was normal except that there was enlargement of the submaxillary and cervical glands. The urine was normal. Examination of the blood showed: Red corpuscles, 4,500,000; white corpuscles, 14,800; hemoglobin, 80 per cent. (sp. gt. method). Nothing abnormal in shape or size of the red cells was observed. The increase in the white cells seemed to be of the polymorphonuclear variety. The eosinophiles comprised less than 2 per cent. of the white corpuscles.

The borders of the disease are everywhere well defined. In some places apparently perfectly normal skin is in contact with a smooth, thin and atrophic integument—doubtless healed areas which had been the seats of superficial involvement of the disease. In other places—where deep scar formation has occurred—the skin is, more or less, wrinkled and the line between the diseased and healthy tissues is less definitely made out. The borders of the disease, corresponding to the areas, the seat of progressive involvement, are not so clearly defined as are the borders of the healed areas, the skin being thickened, reddened and indurated. In some places the diseased areas are markedly elevated. On the right side of the neck a smooth, atrophic area is elevated about 5 mm. above the apparently healthy skin, which is continuous with it. In the median line of the neck is an area with an elevated border, covered with papillary processes which, in places, overlap the normal integument.

Examination of areas, the seat of progressive involvement of the disease, shows papillomatous growths,

abscesses, crusts and ulcerated areas. Microscopically, the papillomatous growths seem to be processes of the corium covered with epithelium. Many cocci and pus corpuscles are found in the abscess cavities. The corium is vascular, infiltrated with leucocytes and round cells, and small abscesses are found containing globular and budding bodies supposed to be yeast fungi. Very few giant cells are observed. No yeast fungi were found in preparations made from the larger abscesses found on the surfaces of the diseased areas. Many small ulcers, from two millimeters to a centimeter in diameter, are found on the right side of the face and neck. These ulcers are circular, with clean-cut borders. The floors of the ulcers are smooth and no undermining of the edges is present. It seemed probable to me that these ulcers were the result of abscess formation due to infection with the ordinary pus cocci.

The lips are so markedly everted that the patient is unable to approximate them. The eversion appears to be caused by the contraction of scars resulting from the disease. The labial mucous membrane shows no evidence of a disease similar to that affecting the face.

Blastomycetic Dermatitis.

The upper and lower lids of the left eye are the seats of the disease in an active state. The conjunctiva and eyeball are not affected. The lids of the right eye present scar formation with contraction and marked eversion of the lids. The conjunctiva is involved in places, especially the upper lid and the outer part of the lower. A cicatrix is found on the inner half of the lower lid. The bulbar conjunctiva is so affected as to render the cornea opaque. No vision is present in the right eye.

The ears are affected with apparently the same process that involves the face. The scalp is involved in the right temporal and left mastoid regions. The process on the scalp seems to correspond to that on the face except that the large abscesses are more numerous and the crust formation is more abundant.

The treatment of this case was unsatisfactory. I was called out of town ten days after the patient was admitted to the hospital, and on my return found that she had left the institution, and I could not afterwards find her. During the time that the case was under my care the treatment consisted of the administration of 20 grains of potassium iodid, internally, four times a day.

Locally, I treated five separate areas differently. One area I curetted and made no applications; another I curetted and then applied a 4 per cent. ointment of potassium iodid in vaselin; a third area was curetted and a mixture of equal parts of tincture of iodine and guaiacol applied; to the fourth area I applied pure carbolic acid, and to the fifth a mixture containing equal parts of iodine and carbolic acid. The fourth and fifth areas were not curetted.

The disease showed improvement in all of the areas treated. The area treated by curetting and applying iodine and guaiacol did better than any of the others. The least improvement was observed in the areas treated by pure carbolic acid, and by curetting followed by the potassium iodid ointment.

### ACUTE ANTERIOR POLIOMYELITIS IN A YOUTH OF 18 YEARS. REMARKS ON THE SENSORY SYMPTOMS.

FRANK R. FRY, A.M., M.D.

Professor of Diseases of the Nervous System, Medical Department  
Washington University.

ST. LOUIS, MO.

A. M., aged 18 years 2 months, was taken with a febrile attack Oct. 13, 1900, accompanied by much pain in the back and thighs, and followed by acute paralysis of the lower limbs.

The patient, an intelligent young man, gives the following account of the attack: On the day he first took to bed he went to school as usual in the morning, although feeling poorly. He was too ill to remain at school, but walked home, a distance of one mile, and went to bed very ill. The next two days he was very restless, suffering especially with pain in the loins and thighs; he was so sensitive to touch that he dreaded to have anyone take hold of him, and it made him sore and tired to lie, and he was in and out of bed frequently. Finally, he could not get up and realized that his lower limbs were paralyzed. Thus, he went to bed Friday after returning from school, and on Sunday he was paralyzed.

He is confident that this painful stage lasted eight to ten days. He instances various collateral data which show that his statements are accurate. After the severe pain there still remained about a week during which moving and touching the paralyzed members, especially the left, caused considerable pain.

During the fourth week after going to bed he discovered that slight voluntary movements were present in the right leg, but none in the left. He did not sit up until the sixth week and then his back was so weak that he could not remain up long.

During the fever stage it was necessary to use a catheter for a day or so, and the bowels were constipated.

Dr. C. A. Anthony, Fredericktown, Mo., the attending physician, observed the case with much interest, remembering the details very accurately for the reason that they were very confusing to him for some days. His account of the onset and the great amount of hyperesthesia and pain in the back and paralyzed members conformed exactly to the statements previously obtained from the patient. No sensory tests were made at the time.

I first examined the patient Jan. 25, 1901, more than three months after the attack. I found a paraplegia of the lower extremities, very little movement in either of them, the right some better and improving faster than the left; but even the right leg had to be lifted in or

out of bed or over the left. He could only get to a chair from the bed and back again with effectual assistance from a strong person.

Dr. M. W. Hoge kindly assisted me in making routine sensory and electric tests. We found all the muscular groups of both extremities more or less atrophied. The most intense atrophy was in the left thigh; apparently, the best preserved group was the calf of the right leg. The flexors of the left knee and foot were becoming contracted, and there was also a slight contracturing tendency apparent in the toes of the right foot. Electrical tests showed a reaction of degeneration, or a partial reaction of degeneration, in all the atrophied groups, the right calf and some of the right thigh muscles alone giving normal reaction. The skin of the feet and legs was cold, clammy, livid; improving in appearance from below upward and better on the right side than on the left. Careful sensory tests (touch, pressure, pain, temperature, etc.), showed slight obtundity, but not more than would be accounted for by the bad trophic state of the skin. There were no dissociate sensory symptoms, except possible pain and temperature sense were a trifle more dulled in the feet than tactile. The general sensation was improved from below upward, its impairment corresponding exactly with the nutritive impairment of the skin. There was no muscle tenderness or hyperesthesia anywhere.

This patient presents another interesting pathologic condition, which probably has no etiological relation to the myelitis, but which we may record as follows: March 31, 1899, he was accidentally shot through the chest, the ball entering to the left of the sternum about the third rib and coming out behind the right clavicle. There is an aneurysm of the arch of the aorta as a result of this injury which causes him no annoyance. He made a rapid recovery after the accident and seemed perfectly well and strong until the time of the paralytic attack which was eighteen months later.

At this writing, eight months after the attack, the patient is hobbling about on crutches, the right leg having improved considerably but the left very slightly.

On account of this patient's age there was an unusual opportunity to obtain an account of the subjective sensory symptoms in a severe attack of acute anterior poliomyelitis. I believe, as do others, that the importance of the sensory symptoms has been somewhat overlooked, and more especially in some of the text-book discussions of the disease. Without attempting an extended consideration of the question I simply wish at the present time to embrace this opportunity of calling attention to it.

Dana<sup>1</sup> thus defines the disease: "Anterior poliomyelitis is a disease of the spinal cord characterized by motor paralysis of rapid onset, followed by muscular wasting, without sensory symptoms. It occurs at all ages but vastly oftener in infancy; hence it is often called infantile palsy."

And Starr<sup>2</sup> thus: "Anterior poliomyelitis is an acute disease observed most commonly among children, but occasionally in adults, characterized by sudden complete loss of power in one or more limbs, followed by wasting of the muscles paralyzed, and by interference of the growth of the parts, but not attended with any sensory disturbances."

Below are quotations from a number of writers whose texts I have picked from my shelves at random:

Hirt:<sup>3</sup> Vague pains in the limbs.

Struempell:<sup>4</sup> The child complains of headache and sometimes of pain in the loins and limbs.

Rosenthal:<sup>5</sup> Sensibility is sometimes exaggerated at the outset but at a later period it becomes normal.

Bruns and Windscheid:<sup>6</sup> Sensation is always preserved, as far as this can be determined in little children. The bladder may be affected in the initial stage, although, of course, this is a difficult matter to determine in very young children.

Oppenheim:<sup>7</sup> There is no pain generally; rarely it may be so acute as to simulate acute rheumatism. The muscles may be sensitive to pressure. If the pain of the muscles and nerves is considerable some neuritis is probably present.

M. Allen Starr:<sup>8</sup> It is generally observed that children cry a good deal during the period of onset, and some of those who are able to complain say that they suffer from pain in the back and in the affected limbs. This pain may remain for some weeks. . . . Retention of urine has been noticed for a few days. . . . There is no complaint of numbness or of paresthesia and there is never any loss of sensation; but the limbs are sometimes painful upon any movement, especially in the joints.

Dana:<sup>9</sup> After the general disturbance subsides there may be some pain in the back and limbs for a few days, and in rare cases the bladder is involved so that there is retention of urine.

Gray:<sup>10</sup> Other reflex phenomena as variable as the fever itself may accompany it, such as delirium, somnolence, convulsions, with or without loss of consciousness, muscular twitchings, vomiting, headache, temporary retention of urine, pain in the loins and in the limbs that are subsequently paralyzed, or general pains. Children of four or five years may be able to locate the pain, while younger ones will only evidence it by crying when they are touched or lifted.

Collins:<sup>11</sup> Usually accompanied in children by manifestations of irritation of the central sensory sphere, such as vomiting, convulsion, flightiness, irritability, and a serious disinclination to be handled, as if pain were caused thereby.

After the general phenomena of inflammation subside, there are no sensory disturbances, subjective or objective, although enduring pains in the extremities have occasionally been noted. When such symptoms occur they indicate an involvement by the inflammatory process of the posterior cornua and the root fibers passing therein.

Ross:<sup>12</sup> Sensory disorders are almost entirely absent during the whole course of the disease. At the outset patients may complain of pains and various paresthesiæ, but these symptoms are of short duration. A certain degree of cutaneous hyperesthesia, or rather hyperalgesia, has been described as being present during the febrile stage, but this tenderness to touch probably depends on tenderness of deeper structures, such as rheumatic inflammation of joints. The cutaneous sensibility is sometimes blunted in the paralyzed extremities in old standing cases, but this probably depends on underlying nutritive and vascular changes.

Church and Peterson:<sup>13</sup> Most writers state that there is a complaint of pain in the afflicted members only rarely, but that, as a rule, sensation in all its phases is entirely normal. It is probable, however, that early dysesthesia, owing to the usual infantile age of the patient and a lack of careful search for such difficulty, has been frequently overlooked. In some considerable number of the cases handling of the affected limbs during the initial fever provoked outcries which were not elicited by similar manipulations of the other members. It is likely that more attention in this direction will show localized hypersensitiveness, or some kindred state, to be usually present and of diagnostic importance. Indeed, complaints of pain and of numbness have been generally noted in older children and in adults, lending, perhaps, undue weight to the usual supposition that such cases are not of a true spinal type. . . .

The adult form is in no way different from the infantile cases excepting the variations due to complete growth having been attained. In anomalous cases the onset of the disease is insidious and the course may be subacute. After infectious diseases one or more limbs may be found useless, flaccid and atrophic, declaring the antecedent myelitis. Occasionally the onset is marked by pains of a severe cutting character, which are frequently attributed to neuritis or to rheumatism, but may be due to irritation of the sensory pathway in the cord

by the location of the myelitic focus backward, involving the neck of the posterior horn.

Peterson:<sup>14</sup> Pain referred to the limbs or back and sometimes even muscular tenderness is apt to be present. The differential diagnosis between peripheral neuritis and poliomyelitis is often difficult in adults, and sometimes indeed, impossible, owing to the occasional prominence of sensory symptoms.

Of the texts above cited some maintain one feature of the sensory phenomena and some another until with them all before us the relative importance of these disturbances may be made out. Only one work gives the subject adequate consideration, namely, Church and Peterson's. My individual experience leads me to recognize the force of the statements therein contained.

In a communication<sup>15</sup> written in 1888, I dwelt briefly upon the sensory symptoms of an interesting case therein reported. Before, and more especially since then, I have been interested in remarking the sensory phenomena of cases of poliomyelitis coming under my own observation, and in those reported by others. I think there is no question that hyperesthesia and pain are both usually present and that they are also usually proportionate to the intensity of the invasion.

In the communication just alluded to I explained the sensory symptoms, as had others, by assuming that there was produced an irritation of the posterior areas of the cord by the overflow of the inflammatory process, whose point of most intense activity was, for some reason which we could then not explain, always in the anterior horns. Collins, Church and Peterson, as herein cited, and others, seem to find this explanation satisfactory. On the other hand some lean to the opinion expressed above by Oppenheim, that pronounced or important sensory symptoms mean a concomitant neuritis. This latter is probably often a hasty supposition, as Church and Peterson intimate. The sensory symptoms of these myelitic attacks are too ephemeral and intense in their duration for even a mild neuritis. They sometimes reach their full intensity within a few hours and are gone within a few days, leaving all forms of sensation quite normal; and secondly, their distribution is not the usual one of neuritis. They infest the back and the proximal portion of the extremities and are not heralded by paresthesias in the hands and feet.

From the above it is evident that these phenomena are the source of some confusion. This is due to the fact that as yet they have probably not been sufficiently studied. The complete absence in typical anterior poliomyelitis of final or permanent sensory disturbances has led us to overlook the significance of those which occur in the onset. For example, in each of the definitions cited above it is affirmed that there are no sensory symptoms attending the disease. This arises probably in the eagerness of these writers to define anterior poliomyelitis as a distinct clinical and pathologic entity, instead of merging it too much in the descriptions of other forms of myelitis, as some clinicians have done. Failing to mention these symptoms at all in a definition under the circumstances would be better than to affirm their absence.

The diagnostic importance of this study is thus suggested by Church and Peterson: "The differential diagnosis between peripheral neuritis and poliomyelitis is often difficult in adults and sometimes indeed, impossible, owing to the occasional prominence of sensory symptoms." With a little pruning this sentence conveys the gist of the discussion. I would say that the sensory symptoms are more than occasionally prominent, and that, while the greatest difficulties of diagnosis need

not arise very often, they do occur frequently enough and are important enough to demand increasing attention. In considering these difficulties we must keep in mind the following possibilities:

1. Cases of acute anterior poliomyelitis with no noticeable sensory symptoms. These are rare, at least in adults and in children old enough to express themselves.

2. Cases of acute anterior poliomyelitis with severe pain and hyperesthesia in the paralytic members in the onset and lasting for a variable time. These cases are also rare.

3. Cases of acute anterior poliomyelitis in which the sensory disturbances fall between the extremes of numbers 1 and 2. These are the usual cases.

4. Cases of multiple neuritis with unusual sensory symptoms and distribution.

5. Cases of so-called "multiple neuritis of the motor type," with little or no sensory symptoms.

6. Cases in which multiple neuritis and poliomyelitis are associated. Such cases have been pathologically demonstrated. They are difficult to diagnosticate; and certainly are not frequent. They are caused by some widespread and intense toxic process, producing grave general symptoms.

7. Miscellaneous conditions, as acute ascending paralysis, "family periodic paralysis," myesthesia, hysteria, etc., which, in the differentiation under consideration, will hardly create confusion when carefully studied.

## SOME CLINICAL ASPECTS OF CHEMISTRY.

CHARLES P. EMERSON, A.B., M.D.

Assistant Resident Physician in Charge of the Clinical Laboratory,  
Johns Hopkins Hospital; Instructor in Medicine,  
Johns Hopkins University.  
BALTIMORE, MD.

Even the most superficial observer of the expansion of the medicine of to-day might accept without much question the claim of chemistry to be the first of the pure sciences which form the foundation of medicine, for the potent influence of its leaven may be perceived throughout the whole medical mass. Clinical laboratories are growing in favor and influence; publishers have produced a superabundance of text-books which purport to "make clinical chemistry easy"; medical journals accept at sight articles on almost any chemical subject, some of scientific value, some of practical value, some of no value.

At a recent large medical congress so much time was spent on the chemical side of internal medicine that one not interested in that subject must have had to exert unusual efforts to look interested and knowing. What did he care what the intermediate products of sugar metabolism are, or whether the body can recognize the difference between a "right-handed" and a

"left-handed" pentose with the same empiric formula? Of what "practical value" is it to discover an extra ferment in the stomach? Does the "practical man" care to know how a hen synthesizes uric acid?

Neurologists now examine urine with greater interest and demand that we find there the cause of a neuritis. Oculists and dermatologists awake to the fact that the whole body is one and that the chemistry of this whole may throw light on the organ in which they are interested. Students are required to take chemical courses before beginning to study medicine and it is a professor of anatomy who suggests the addition of another year of pure chemistry to the already long list of requirements of one school.

But chemical education does not emanate alone from medical schools, medical journals and medical congresses; every practitioner gets a free course through the mails. He is bombarded with pamphlets giving a detailed account of some recent "Arbeit" in chemistry, and advertising a new food or new preparation of some well-known substance, or some brand-new drug which is the tangible and expensive embodiment of the above-mentioned "Arbeit." The whole practical medical world, in fact, is studying chemistry.

But it is not alone medical men who are turning chemists for the pathologists are also studying chemistry—their hemolysins, bacteriohemagglutinins, anti-hemagglutinins, toxophores, heptophores, complementophilic groups and intermediary bodies are now or soon will be playthings of "pathologic chemists."

The physiologic laboratories have also felt the leaven. The kymograph is run down, the plethysmograph leaks, the nonpolarizable electrodes almost spark, burettes, test tubes and beakers cover the tables, for the physiologists are, many of them, studying chemistry. Here the recently-called professor of physiology is a pure chemist; there almost the whole physiologic staff is working on chemical problems. The journals which publish the mechanical side are termed by a pure physiologist "uninteresting," journals of physiologic chemistry grow in number and circulation and the physiologic chemical laboratories are admitted by eminent clinical men to be the centers from which the medicine of to-day is progressing.

The growth of the physiologic chemical laboratory is of the utmost importance to clinical medicine, for now the clinical laboratory will be provided with methods which are of practical use to the clinical man, and with men well enough trained to use them. Clinical chemistry is no new subject. Urinary examination has long been recognized as of the greatest importance, but the work has not been done by men especially fitted and the methods in use were many of them poor. Nevertheless, and in fact because of this, there has grown a very extensive literature of clinical chemistry and to increase this has been one of the earmarks of a "very scientific practitioner." The advent of physiologic chemistry, the occupation of the field by thoroughly-trained men, has sifted and weeded this literature to a surprising degree. Instead of a long list of diseases in which the xanthin bodies are increased or diminished we now read that the method used was so inaccurate that "our knowledge of the relations of xanthins to pathologic processes is as defective as it was years ago": the alkalinity of the blood is not arraigned as often as a few years ago, although we still suspect it is an offender, but can not prove it; phosphaturia is now a name only. Compare a text-book of clinical chemistry of this year with one

\* Read before the Clinical Section of the Medical and Chirurgical Faculty of the State of Maryland.

of a few years ago and see how much less we know now than then.

The advances already made by study of the chemical side of internal medicine are great. Metabolism experiments in various diseases have thrown considerable light on the nature of these conditions and in the sphere of dietetics aided the practitioner to no small degree. They were clinical chemists who showed the importance of the test meal, the meaning of the hyperacidity and anacidity, of free and bound hydrochloric acid, the significance of lactic acid and lastly the importance of the increased bound chlorids in the early diagnosis of cancer of the stomach (Reissner). It was a clinical chemist who showed that in the pneumonic lung the exudate was digested as if it were a piece of meat in the intestine, and that from examination of the urine the amount of lung resolved could be each day weighed. The practical results from this may be considerable. They were clinical chemists who taught the profession so much about diabetes mellitus; a short review of this subject will be a good illustration of the contributions of clinical chemistry. The presence of sugar in the diabetic's urine had been long known and its amount followed by clinical chemists, but does this explain diabetic coma, the dyspneic coma of Kussmaul? Petters ascribed this to acetone, Gerhardt to a body later found to be diacetic acid, but neither of these is the poison, yet the qualitative tests of these are of great value and can be easily and repeatedly made by every practitioner in every case of diabetes. Following a suggestion from a pharmacologic laboratory Hallervorden demonstrated the increase of ammonia in the urine of diabetics—and in each severe case this quantitative determination should be made at stated intervals—this increased ammonia proved that in the urine was an increase of acid. Stadelmann proved this acid to be organic, showed the relation between its increase and coma, pointed out the similarity between diabetic coma and that of rabbits with acid intoxication (Walters), and deserves the greatest credit for introducing the alkali treatment of diabetes. It remained for clinical chemists, Minkowski and Külz, to isolate this acid, which they found to be oxybutyric acid, from the decomposition of which acetone and diacetic acid arise. The discovery of this body must have surprised chemists. They had interested themselves in many bodies present to about one-half a gram or less, and overlooked this often present to the amount of 20-30 gms. and in coma even one-quarter of a pound a day!

Before the alkali treatment, when rigid diet of diabetics was enforced, the practitioners noticed that many patients promptly went into coma and died—why? Again clinical chemists answer. That acetone and diacetic acid are present in a normal fasting person, or a patient with almost any disease causing severe malnutrition, clinical chemists had noticed. Gerhardt and Schlesinger then showed that a normal person who eats the diabetic's rigid diet will, on about the seventh day, show even nine grams of oxybutyric acid in his urine. Since this acid is then a product of metabolism of any person when the diet is too poor in carbohydrates, what wonder then that the diabetic, already on sugar-rich diet half poisoned by it, should, when sugar is withheld, at once succumb to the increase of this acid? How necessary it is that the practitioner should know whether or not his patient is already in a condition of partial acid intoxication, by the simple tests for acetone and diacetic acid, and, if this is the case, should give an abundance of sodium-bicarbonate, not "fifteen grains

with each meal," but even that number of grams and govern the size of the dose by the amount of the ammonia, for it is the absence of alkali which forces the body to increase the ammonia in the urine, and the accurate amount of this any practicing physician can determine, if he will. But physiologic chemistry (Hofmeister) has called the attention of clinical chemists to the importance of determining the assimilation limit of the patient and the diagnosis of diabetes mellitus is now made when the urine is sugar-free. Lastly, glycuronic acid is now well proven a first product of sugar metabolism and to find this increased, even though sugar be not present, may soon be ground for rejection by insurance companies as diabetic.

The above are a few of the contributions of chemistry, but it has only begun its serious work and promises much greater results.

We hope that one of these will be to convince the medical world that eggs and milk are not only a good, but the best diet for a patient. At present the tendency is to prescribe predigested proteids, various peptone preparations and many other specially prepared foods, so that in a long fever the bill for these may well appall the wage-earner of the family. Nevertheless, it is questionable whether there is any good evidence in favor of such foods, which justifies such expense. Certain it is that their superiority over simple eggs and milk has scarcely any, if any, physiologic basis. It is not proven that albumoses have even the same nutritional value as the native albumins of milk and eggs, or that these latter if properly given are at all hard to digest. As for "peptone" each new work seems determined to destroy our faith in it as an important product of digestion (Zuntz and especially Cohnheim). Meat extracts may have a stimulating effect and do, hence the certain benefit which the patient derives; but as for their nutritional value, one may as well feed a fire from the ash heap. On the whole, we can assert that the weight of physiologic evidence is against artificial foods, including in that list all predigested foods. Predigested they may be for a test tube but not necessarily for a patient—the normal body and more so the diseased, demand albumins. These it digests to suit itself, breaks them down to amidoacids and then synthesizes these to the proper albumin and at the present state of our knowledge it is much better to furnish even the diseased body with the raw material than to try to aid it by furnishing products of artificial digestion which, so far as we know, it can not use. Clinical evidence that such foods are unnecessary may be obtained from Dr. Osler's wards where they are never given. Seldom it is that a patient can not digest properly diluted milk, still less seldom that he can not well-prepared egg albumin or beef juice. Of course, the tendency now, when few medicines are prescribed, is to prescribe foods, but the practitioner may well bear in mind that their nutritional advantage is questionable, the chief person to benefit being the manufacturing chemist, and that eggs and milk, if properly prepared, may be even superior and do not cost one dollar a bottle.

One of the most promising fields for clinical chemistry is anemia and it is of interest that hematologists are turning from the morphologic to the chemical side. We read less now of blood counts in pernicious anemia, more about specific gravity, potassium and sodium percentages of the plasma, fat determinations, etc. This is only natural as the plasma is by far the most important part of the blood; red corpuscles, and leucocytes also per-

haps, have a very limited function compared with that of the plasma. When in a case of anemia we count the reds, determine hemoglobin and estimate the percentage of eosinophiles and lymphocytes and polymorphonuclear neutrophils we gain excellent clinical information, but so far as approaching the question of the anemia we have only begun—the cause of such changes as we find lies farther back in the plasma or blood-forming organs, and in the latter case the plasma may still be to blame. Ask a student what the hemopoietic organs are and he will doubtless answer, bone marrow, lymph glands and spleen, thus omitting three just as important. I think more so, intestinal wall, liver and kidneys, for these determine the composition of the plasma. No, chronic anemia is not oxygen starvation. Clinically, we must depend almost entirely on a study of the morphologic elements, but the laboratory worker must and is already going much further and over two-thirds of the recent communications on blood have dealt with its chemical side.

We read much and hear more lately of the practical value of blood examination. Some would give it first importance evidently as much as the physical examination of the patients; some, because they can not rely on it alone, deny it any importance, while others insist it is of value when well done and rationally interpreted. It is certain that blood examination to many means merely leucocyte counting. Our experience may be briefly stated: In practical internal medicine, leucocyte counting is invaluable. In surgery it is very important, usually throwing some light on the case; sometimes it alone determines the course of action, on other cases its evidence is disregarded. In all cases it must be interpreted by one who understands that leucocytosis is a biologic chemical reaction, hence must not be asked to conform to mathematical standards as a purely chemical reaction might be. He also should be one who has made just a few leucocyte counts himself and knows whether or not a slightly higher count means a rise of leucocytes. Counting red corpuscles is in internal medicine very valuable. Hemoglobin determination is for both physician and surgeon indispensable. Differential leucocyte counting is for the physician always of interest, often of considerable value, but will never have the importance claimed for it until the chemist has shown us the "why" of our staining reactions, and the physiologist the origin of the cells. Further blood examination, alkalescence, the composition of the plasma may in the future be a matter of routine, but at present they belong to the clinical chemist.

But one point deserves further mention and that is the staining reactions of the blood cells. Following Ehrlich's work we have in the past few years learned another language, the nomenclature of blood staining. We are asked to recognize amblychromatic and trachychromatic nuclei, to distinguish carefully between eosinophilic and fuchsinophilic reds and not to mistake the latter for polychromatophilic degeneration. This little thread of chromatin is the trademark of bone-marrow-made cells; this cell is the daughter of that: these have no relation. With each new stain are the granulations multiplying rapidly and, worst of all, the technic is long and results uncertain. And what does it all amount to? With all these studies in stains do we know much more than a fresh specimen would teach us? With all these names which label cells with a source, do we know any more of the origin and relationship of leucocytes than Virchow knew fifty years ago? Very

little. I don't wonder Ehrlich changed the subject. Has since the work of Neumann and Bizzozero one well accepted fact been added to our knowledge of the origin or the structure of the red corpuscles or their relation to the leucocytes? No. Is it necessary for the busy practitioner to spend hours getting his stained specimens? A most emphatic, no. We have satisfactory methods which give beautiful specimens in three minutes, and he doesn't look at fresh specimens nearly long enough. A trained man can guess at a blood-count and hemoglobin percentage and often get it closer than a less experienced man can with counter and hemoglobino-meter.

And the uric acid diathesis. What shall we say of that? Can clinical chemistry deal it any harder blows than it has received? Yet many still would insist that uric acid is really important. Thirty-nine separate morbid conditions are already ascribed to it and the fortieth recently added by an oculist, astigmatism against the rule! Now we know something, not much, about uric acid. We know it is a product of metabolism of proteid. We know the body can also form it by the synthesis of simpler bodies. We know no small part of that which is excreted is from similar bodies in the food and, lastly, that the body can oxidize uric acid. Hence it can not be considered the criterion for the metabolism of any one proteid body. We deny any relationship well proven between an increase of uric acid and leucocytosis; we deny that an increase has been well proven in any disease except fever and leukemia. We do not doubt but that the clinical picture is well marked which bears the name uric acid diathesis, but we do ask does uric acid have any more to do with it than has science with "christian science"?

In conclusion I make a plea for the more general use of the clinical laboratory. The practitioner depends on the bacteriologic laboratory because he knows he can not do this work. Should he not depend almost as much on the clinical laboratory? There are no tests more frequently made by a practitioner than the albumin and sugar tests; can he do these in a doubtful case? He should the former, yet we are certain many a faint trace escapes notice, but the latter he can not in a doubtful case, do, and not now so well as he could a few years ago. An illustration may explain this. Not long ago a patient in a distant city brought us a bottle of urine with the question, "Is sugar present?" The urine reduced copper fairly well, Nylander's test was decidedly positive. Here the physician must have stopped, yet these two tests do not prove sugar. The urine was not dextro-rotatory, it would not ferment, an increase of glucosazon crystals could not be determined, and in a doubtful case all of these tests should be found positive before glycosuria is diagnosed. But what was present? The patient when questioned solved the difficulty. When told to send another specimen and to add camphor to keep it in good condition she replied, "But my doctor told me something much better than that, he told me to add formalin." Formalin is the aldehyd of formic acid, glucose the aldehyd of sorbite and they both reduce copper and bismuth well. I then read clinical chemistries on the subject. One, the most pretentious in this country, advises to add a few drops of formalin to the urine to preserve it. If this advice is followed and it certainly will be by many, what will save the practitioner from finding sugar in many urines? Of course, we know that the text-book says "two or three drops, not more," and a very few drops in a twenty-four-hour specimen will not

trouble the chemist very much, but the "two or three drops" in a four-ounce bottle of the patient who wishes to do the matter thoroughly will, and in this case did, give a splendid reduction test. Almost at the same time another specimen was sent. It reduced copper and bismuth well, but the practitioner was sure it was not glucose, it must be lactose since the patient was pregnant. If lactose, its presence was of no moment; if glucose, of the greatest moment. Hence we say the practitioner in a doubtful case often needs a clinical chemist to aid him, especially if he believes in Nylander's test and allows his patients asparagus. In this connection I would say that one of our students recently showed us that thymol, an excellent preservative for urine, can impart to it good Gmelin-bile-reaction-giving properties. If the practitioner has sent to him a highly-colored urine with a crystal of thymol in it let him beware of making the diagnosis of bile in the urine. The practitioner, on the other hand, does not do nearly enough of some chemistry. With a few test tubes, reagents and a burette, he can do a surprising amount if he will, but let him send doubtful cases to the expert—and cryoscopy to any one with more time than he.

## A PLEA FOR THE EARLY TREATMENT OF SQUINT.\*

NELSON MILES BLACK, M.D.

MILWAUKEE.

The majority of laymen and a great many of our professional brethren regard squint with a great deal of indifference. This arises largely from the prevalent idea that the child will outgrow it, is too young to be treated or, if treated, will have to always wear glasses. Yet when children grow up with this horrible deformity, they and their parents often seek for relief without success. What I wish to try to make clear is the fallacy of the above reasons, why the squinting eyes of children should be attended to as soon as the first appearance of even a tendency to squint is noticed.

1. In rare instances in some cases the squint disappears as the patient grows older, but nearly always with vision much impaired in the deviating eye and binocular vision very imperfectly developed.

2. The earlier one can get a case after he has commenced to squint, the better the prognosis as to the parallelism of the eyes, binocular vision and visual acuity of each individual eye, because the case is in the developmental stage.

3. In regard to wearing glasses, the contrary is true. If a case can be obtained for treatment soon enough after the squint is noticed, the glasses, in the majority of cases, can be laid away about or soon after puberty, being only needed for close application of the eyes, except, of course, in cases of high hyperopia, myopia or astigmatism.

These deductions are reached through the latest theory advanced by Mr. Claud Worth of London regarding the etiology of squint, i. e., that the potential factor in the cause of squint, of course taken together with the several other etiologic factors, as hyperopia, myopia, anisometropia, congenital amblyopia, fundus changes, changes in the refractive media, heredity, local changes in an ocular muscle, etc., is the defective or non-development of the fusion sense.

We all know that binocular vision is produced by similar portions of the retina being acted upon by rays of

light and these afferent sensations fused centrally. Now, if the condition of the eyes is such that through hyperopia, myopia, anisometropia, congenital amblyopia or any of the above enumerated etiologic causes, which produce central sensations of different intensity, the sensation carried to the brain by the poorer eye can not compete with the clear, distinct image of the better eye and is disregarded, as we disregard the image formed by its fellow when we use the microscope with both eyes open; the eye is thus without a point of fixation and turns in or out. This occurring at a time when the fusion sense is in the process of development and the eye receiving no help in the way of improving the retinal image so it can compete with the fixing eye, the fusion sense is defectively developed or lost, and the eye remaining in the mal position, the squint is established and the organ becomes more and more amblyopic from non-use. The eye usually turns in in hyperopia as the relation of convergence and accommodation converges the visual axis. Instead of both eyes appearing to converge equally, the better eye fixes and the poorer eye turns through the additional arc to allow of this fixation. This explains also the so-called alternating squint, when the patient fixes with one eye or the other, the one eye turns through an additional arc to allow its fellow to fix. In myopia the general tendency is for the eyes to diverge; this is explained on the ground that the myopic eye not having to accommodate there is no effort to converge, consequently the eye diverges.

Then come the class of cases where there are no refractive errors or any of the before-mentioned etiologic factors; yet the child squints. The history of these cases usually develops that the squint commenced after a fright or during an attack of whooping cough or followed some severe illness, and is explained by the fusion sense being in a rudimentary state of development; it is thus rudely interfered with, the fusion center greatly disturbed and binocular vision thus lost for a time and one eye or the other allowed to deviate from parallelism.

The fusion sense, Mr. Worth has determined, is fully developed by the sixth year; after that the question of establishing it is almost beyond hope.

The factors to be dealt with in a case of squint are:

1. The deformity. 2. The suppressed vision of the deviating eye. 3. The more or less amblyopic condition of the deviating eye in the majority of cases. 4. The refractive errors. 5. The fusion sense.

The suppressed vision of the deviating eye produces a loss of central fixation, that in turn causes a deterioration of the vision in the deviating eye, as the rays of light are focused on other portions of the retina than the visual center or fovea and the eye becomes amblyopic; so in our treatment the first step is, after measuring the angle of the squint, to prevent the loss of central fixation and so prevent deterioration of the deviating eye. This is accomplished by refracting the eyes, fully correcting the hyperopia, myopia and astigmatism and ordering glasses to be worn constantly. The determination of the visual acuity is first desired for refraction and this is accomplished in cases who are not old enough to know their letters by the aid of five ivory balls, from  $\frac{1}{2}$  to  $1\frac{1}{2}$  inches in diameter in the following manner: By covering the poorer eye of the patient and starting a game of marbles with him. The mystery is solved! If at 5 meters he can go directly for the smallest ball without hunting about for it, it is safe to say his vision for that eye is about normal, then trying the other eye in the same manner, its visual acuity is determined approximately.

\* Read before the Milwaukee Medical Society, April 22, 1902.

The errors of refraction are then determined under mydriatic by the skiascope. The child's disposition has a great deal to do with his wearing the glasses, but in cases of considerable degree of refractive error (3 and 4 D.) no trouble is experienced. I have seen 18-month-old babies with glasses who would commence to cry as soon as the glasses were removed and would stop the moment they were replaced.

After the visual acuity is brought as near normal as possible the next step is exercising the deviating eye. This is done by bandaging the fixing eye continuously for a long period of time (which the majority of parents will not do), or better still, by the use of a mydriatic in the fixing eye to abolish its power of accommodation. The child will then fix for near objects with the deviating unatropinized eye, and use the atropinized eye for distance. Thus amblyopia from disuse is avoided. The parents find no trouble in instilling a drop of some mydriatic solution in the eye each morning, but seriously object to the child's eye being continuously bandaged.

Amblyoscope and Series of Slides.—The bird and cage being used to establish binocular vision only. The second set requiring true fusion to complete the picture. The last when fused gives an impression of the perspective.

In cases where the vision of the deviating eye can not be made to compete with the fixing eye, then continuous-occlusion must be resorted to in order to bring about central fixation. If this has been lost only a short time, two or three weeks is usually sufficient to restore fixation, but in neglected cases, where the eye has become quite amblyopic and central fixation has been lost for a long time, much improvement can not be expected, although some surprising results are accomplished. A mydriatic used in both eyes is worse than useless, as the visual acuity remains proportionately the same and although the eyes seem straight under the mydriatic, it is only because the accommodative effort is paralyzed and consequently there is no effort to converge.

The fusion faculty is next exercised by the ingenious instrument devised by Mr. Worth called the amblyoscope. This instrument consists of two halves joined by a hinge, each half consists of a very short tube joined to a longer one at an angle of 120 degrees; a mirror being placed

at the cord subtending the arc of this angle; an object glass is placed at the free end of the longer tube, at the free end of the shorter tube is a lens, the focal length of which equals the distance of the reflected image of the object glass at the end of the longer tube. "The two halves of the instrument can be brought together to suit a convergence of the visual axes up to 60 degrees, or separated to suit a divergence of as much as 30 degrees."

"The pairs of object slides are drawn on translucent paper and stuck on glass slides. These are of three classes. The first class consists of pairs of devices, such as a bird and a cage, a mouse and a trap, etc. These require no blending of images, but only binocular vision. The second class consists of devices, part of which are on each slide, so that a blending or fusing of the images must take place in order that the full picture may be seen. The third class consists of stereoscopic pictures, which when combined give an impression of perspective."

The instrument is used in the following manner: "The child with his correction on is held on the surgeon's knees and the amblyoscope roughly adapted to his degree of deviation; it is then held before the child's eyes and an electric lamp is put in the axis of each tube about four feet away. By a simple mechanical arrangement each lamp is easily brought nearer to, or put farther away from the tube which it illuminates. A slide showing a cage, for instance, is put in the tube before the child's fixing eye, and a bird in that before the squinting eye, and the child is told what to look for. At first he sees only the cage. The lamp before the fixing eye is then taken farther away, and that before the squinting eye is brought nearer until the child sees the bird. By this time he has lost sight of the cage. The intensities of the illuminations are then adjusted until the child sees both the bird and the cage. The child is then allowed to grasp the instrument and, assisted by the hands of the surgeon, is taught to vary the angle of the instrument so as to make the bird go in and out of the cage. Many other similar pairs of slides are shown. The average child of 3½ or 4 years of age takes a very keen interest in the game which he imagines has been devised merely for his amusement. Slides which require a true blending of the images are then shown. After a time it is often found that the angle of the instrument may be altered to a very considerable extent, either in convergence or divergence, while the eyes follow the objects and maintain fusion of the pictures. One often gets a powerful "desire" for binocular vision in these young subjects with surprising facility. The next step is to equalize the intensities of the lights. This may usually be done at this stage without a return of suppression. In many cases one is able to deviate the two halves of the amblyoscope more and more at each visit until parallelism of the visual axes is obtained. In other cases operation may be necessary. If, then, the eyes are placed approximately straight, the desire for fusion will fill up any slight gap that may remain. However the actual remedying of the deviation may be affected, if the child has this powerful desire for fusion, which can only be acquired in early childhood, a perfect cure of the squint results. The child will then, in the majority of cases, be able after a time to lay aside his glasses except for reading."

The use of the stereoscope with properly selected pictures, after the visual axes have become parallel or the eyes have been straightened by operation, will greatly aid in the exercise of the fusion center, but is of no avail before the visual axes are approximately parallel. Dr. Würdemann's modification of Kroll's orthoptic ex-

ercises in black and white are especially adapted for this exercise.

"The special points of the amblyoscope are: 1. It is adapted for the use during the continuance of a squint of any degree; 2, the suppression of the vision of the deviating eye is quickly overcome by the unequal illumination of the object slides, instead of by the slow and painful method, recommended by Javal and others of continuous occlusion of the better eye for months or a year at a time; and, 3, the variety of the pictures amuses and interests the child, so he will give all the help he can."

To summarize: The treatment of squint should commence as soon as the slightest deviation of the eyes is noticed and should consist of:

1. The maintenance of fixation in the deviating eye to prevent deterioration of vision in that eye.

2. The correction of all refractive errors.

3. The exercise of the fusion faculty and when that is well developed, if the deviation is not corrected, resort to operative measures to produce approximate parallelism of the axes; the desire of fusion developed by the exercise of this center will then maintain parallelism and binocular vision.

105 Grand Avenue.

### ATTENDANTS AND NURSEMAIDS.\*

LESS EXPENSIVE AND LESS EXPERT SERVICE NEEDED—  
CLASSES BY PHILANTHROPIC ORGANIZATIONS—MEDICAL INSTITUTIONS FOR THE SICK THE PROPER  
ONES TO GIVE SUCH INSTRUCTION—THIS  
GRADE OF HELPERS WOULD RAISE THE  
STANDING OF GRADUATE NURSES.

HELEN C. PUTNAM, A.B., M.D.

PROVIDENCE.

There is a wide-felt need and legitimate demand for women to care for the sick who shall be less expert and less expensive than graduate nurses. Among those of generous fortunes the demand comes from chronic invalids needing waiting on for months or years: from victims of slight ailments, as a broken arm or brief exhaustion in overwork; from tardy convalescents of all grades of income above the very small (who must get well as they can). Graduates usually, if not always, do not wish to take these cases. A not less pressing demand comes from the large army of families, self-respecting bill payers, living on \$500 to \$1500 a year, to whom \$18 to \$30 weekly is a heart-aching burden almost impossible for even two or three weeks; where the mother's hands "keep" the house, and it is perhaps she who is laid by. Visiting nurses can not satisfy this demand (resident service is wanted): nor can hospitals by sending undergraduates; and such families are far from being objects of charity. Its supply has come mainly from obliging friends and "experienced nurses," the number of the latter being far from sufficient and the capabilities of all wholly uncertain.

To fill the need various philanthropic societies, such as women's educational and industrial unions and young women's Christian associations have recently conducted "classes for training attendants" or "for home nursing," where, at an expense varying from \$10 to \$30 for each pupil, a course of twenty to thirty evening lessons (of one or two hours) has been given by a graduate nurse, sometimes including lectures by physicians. Occasionally five to ten lessons in invalid cooking supplement

it, and visits with a district nurse or to the city hospitals. The lessons consist of lectures or text-book work, note-taking, quizzing and a little manual drill in care of a bed and of a "patient" (model) in bed, handling of bed-pans and douche-pans (dry), syringes, thermometers and medicine glasses, and plain bandaging.

The pupils are workers in offices, factories, stores, sewing-rooms or kitchens; sometimes an "experienced nurse," a housewife, a schoolgirl, and often unoccupied women. Ages are nominally from 18 to 40, actually from 15 to 60; education nominally required equals first year of grammar school, but actually ranges from bare ability to read easy English and write with difficulty up to that of a well-educated gentlewoman. Moral and other personal qualifications have as wide a range. Some classes limit membership to twelve, others have as many as thirty members. The examinations and certificating are equally elastic, such courses being subject to the pecuniary, philanthropic and impulsive irregularities that invariably obtain outside of any but an organized school in a hospital or sanatorium of recognized professional standards.

Some take the course for use in their own families; others to make nursing their work; others to do occasional neighborhood nursing, a congenial field of usefulness that gives them a little income to add to home comforts; and others take it as a part of an intelligent woman's education. It is with this last idea that our very few pioneer schools of housekeeping and our manual training public high schools are offering excellent short courses in nursing. Young women occasionally take the attendant's course to make their first year easier in the training school, often by the advice of a graduate; or "discover themselves" in the course and elect to go on to regular training. Some of these testify that the theory and invalid cooking are better taught outside, as is quite probably true, organizations often selecting expert teachers from among the best in the city. Such facts are suggestive to managers of training schools. So pressing is the demand for less expensive (and less expert) care that, although many such classes "pledge" their graduates to charge but \$5 or \$7 weekly the first year (while "getting experience"), it is a fact that some charge within six months \$10 to \$15 because they can get it. Of course more receive only \$7. The claim to "have a certificate" satisfies those who could and would nurse their own sick if they but had another pair of hands. They save from \$13 to \$3 a week (from graduate's pay) and obtain the help they must have.

What kind of help? As to quantity, they have probably a reasonable amount of service about the home when the patient does not require attention. This is what the family needs, and from an humanitarian viewpoint it should be so—so far as it does not overtax the helper. As to quality of nursing, it is precisely what would be expected from such varieties of "standards" and of pupils, after thirty to fifty evening hours of instruction, chiefly theoretical. However willing, anxious for personal credit, enthusiastic out of pure altruism, they may be, it is the exceptional women who earn (economically speaking) \$7 a week and board; and they quite often deserve it without "the course." It is usually the smallest wage-earners (therefore the more incapable) who take it up as a business. The average attendant does not equal the average "experienced nurse" or the average mother, either in judgment, reliability or capacity, the lack being chiefly along the line of experience. The majority of mothers can, by

\* Read before the Providence Medical Association, Feb. 3, 1902.

following the visiting physician's directions, use the clinical thermometer; or give an enema, a douche, a sponge bath with more skill. Another serious defect is the unconscious assumption of too great responsibility, because of inefficient instruction as to limits of initiative and as to accuracy in reporting. Physicians must ordinarily accept the caretaker a family provides and naturally believe that she can render the simple service claimed. A tidy room, pleasant manners and friendly relations with the patient innocently deceive concerning the necessity of minute inquiry into omissions and commissions.

Not unreasonably graduate nurses deplore this movement, as is indicated by several paragraphs in their official organ, *The American Journal of Nursing*. The time has arrived when friends of training schools for nurses and of the people would do well to try to adjust the matter more fairly.

It would show good business sagacity on the part of medical institutions for the sick to supply this demand and so "control relative market values"; and good judgment to acknowledge its legitimate existence and therefore their willingness to serve society by preparing caretakers of simple ability and price. For "lay" organizations to undertake what should be the function of medical institutions is another instance of waste of philanthropic resources, the hospitals having already secured, usually by gifts, the material equipment and educational qualifications for instructing in care of the sick, while "the laity" must divert still more charitable effort in crude attempts along similar lines. Since the popular need as outlined is a very large and just one, both common sense and professional enterprise indicate hospitals and sanatoria as the proper agents to fill it.

Nursemaids for children, who shall have rudimentary scientific and manual training, are also in demand. The day of unskilled service for making homes and laying the foundations of adult careers is, happily, dying. Science simplifies serving. There is no lack of women able to take in the necessary instruction, and to fill situations for wages on a par with average house service. It requires certainly no rarer mental ability than that of good waitresses and cooks and not so much muscular strength; it is a matter of fact that the "second girl" who "likes nursing" often learns to do very acceptably such of it as she has time for, but necessarily her regular work suffers. It is more congenial—either the care of invalids or of children—to many temperaments which at present recruit the ranks of inefficients. Their ability is of an order that may be turned to use by a few months of careful instruction, for which a temporary home and \$3 to \$8 or \$10 a week is good remuneration in comparison with that in some other occupations which require even more preparation.

It would be a mistake in such a course to encourage narrowness of ideas as to range of services and rate of wages. An attendant who gives grudgingly of needed help, especially in modest homes, where the invalid does not require all her time, lacks the quality of effectual sympathy indispensable in a service so personal and so humane. It is carrying "specialization" to unrighteous limits that belittle character.

This undertaking should not conflict either with training-schools or with philanthropic efforts. Of the latter I venture the prediction that, if a hospital opened a minor course in nursing, a frank explanation to the organizations already offering these classes would meet with the enlightened coöperation desired, probably withdrawal of its own course and influencing women to

avail themselves of the better facilities, with one proviso, viz., that the hospital offer a course that *accords with the need*—faithful simple manual service, good as far as it goes, and going far enough for non-critical illnesses and for slender incomes.

Instead of undermining the dignity and valuation of expert nursing by poor and over-paid service, these attendants would help teach sanitary knowledge to larger numbers, and create higher ideas of the superior rank of nurses. There would be a defined grade between the latter and "chaos," tending to encourage development "at the top," where there is always room.<sup>1</sup>

Attendants secure work through the individual influence of members of the large associations offering the courses and through their registers; or, often, through their own acquaintances who are frequently of the class, as has been already intimated, who have not been a "field" for graduate nurses.\* They rarely use the regular public registers. Just what conditions obtain in Philadelphia I do not know; but, in the great majority of cities, action such as the recent one of exclusion from the register of the College of Physicians would have a moral and theoretical influence, but no appreciable effect upon the actual employment by the public of minor nurses. *Laissez faire* policy is apt to accomplish little in comparison with wise aggression. "Classes for training attendants" are a natural growth the object of which is not to supplant but to supplement regular training schools along a line where hospitals leave a large public need unfilled. The "wise aggression" would be to coördinate the two, under professional management, to avoid trespass and many other injustices.

This logical enlargement of hospital service to the community would have inertia chiefly to overcome and some active opposition. A medical superintendent of tact and executive initiative could so demonstrate its wisdom and practicability, that public opinion would place his experiment at the head of an educational movement in hospitals corresponding with the twentieth century popular movement towards more general understanding of scientific subjects—one of the best possible preventives of quackery and *antis*.

The teaching force can be recruited if necessary, and probably advantageously, from city nurses and physicians; many a free-bed convalescent will gladly earn a fee by serving as model; tuition expenses must be small; hours must be adjusted by the fact that the pupils usually have regular occupations. Whatever flexibility in admission may be expedient, there should be rigid adherence to the standards adopted, an important part of the necessary moral disciplining; and the actual conditions be thoroughly studied in order to train women satisfactorily. Finally such an *esprit de corps* needs to be organized (possibly by a club, a uniform, or, better, a badge bearing the name or symbol of the order) that they will take pride in maintaining just relations with graduate nurses, as much as with physicians, and, as to patients, will be mindful of their mission of helpers in homes. A simple and attractive name should be devised, "nurse" being substituted now by families in place of the formidable trisyllable "attendant."

The superintendent of a training school who sympathizes as intelligently with the need of the people as she does with upholding the standards of her school, has in

1. See Dr. Cabot's paper, Boston Med. and Surg. Jour., Nov. 21, 1901.

\* They do not work among the very poor, whose usually greater needs are beyond an attendant's ability, and who are, as a rule, provided for by visiting nurses and hospitals.

this a fruitful opportunity to minister to altruism. Chronic cases, slight ailments and thrifty people on small incomes furnish the larger part of physicians' practice. The public must of necessity have workers in this field, if not instructed, then "experienced" or otherwise as hitherto. Artificial limitations of teaching that every home-maker ought to have should not and can not prevail.

This article is not to be misunderstood as advocating lesser preparation or prices (although prices might well be more adjustable) for nurses ranking like the present graduate. The three logical and practicable grades of nurses are "attendants" for light nursing, for nurses' assistants, and for nursemaids; "graduates" for serious illnesses; and nurses of more advanced training for institutional work (in army, training schools, asylums, hospitals, public health departments, philanthropic aid societies, etc.); as, for instance, the majority of people leave school with a "working basis" for "every day," fewer are graduated from college equipped for more specialized service, and fewest go on to advanced professional schools.

### THE EVOLUTIONARY ASPECT OF INFECTIOUS DISEASES, WITH ESPECIAL REFERENCE TO THE LOCAL VENEREAL DISEASES.\*

G. FRANK LYDSTON, M.D.

Professor of the Surgical Diseases of the Genito-Urinary Organs, Medical Department, State University of Illinois; Professor of Surgery, Chicago Clinical School; Surgeon to St. Mary's Hospital.  
CHICAGO.

(Concluded from p. 1291.)

The light factor of environment is very important in the life history of micro-organisms. In general, bacteria flourish and wax fat in the absence of light. To many pathogenic micro-organisms light—especially direct sunlight—is fatal. In rare instances, as in the case of Englemann's bacterium photometricum, light increases activity. I know of no pathogenic germs in which the reverse does not prevail in greater or less degree. That temperature is an important factor in micro-organic life is so familiar that I would not allude to it were it not so vital in its relations to the evolution of infection. Bacteria have been found that multiply at 0 C. Certain water varieties spore in water covered with ice and freezing does not kill them, but most soil and water bacteria thrive best at about 20 C. although they begin to multiply at a lower point. Germs have been found which grow only at a temperature high enough to alter proteid, 54 to 57 C.<sup>5</sup> It is evident to any one who does not accept the Mosaic cosmogony that the primal environment of the micro-organic world was relatively warm and almost if not quite uniform. The variation in temperature requirements which we observe at the present epoch means a gradual differentiation and a slow but certain adaptation to environment which always brings in their train new properties, be the germ pathogenic or non-pathogenic.

Some of the laboratory experiments proving the necessity of special conditions in the life history of pathogenic microbes are very pertinent and suggestive. Take, for example, that most virulent disease, anthrax. Dogs succumb to it only when pure cultures are injected intravenously. Young rats die of general infection while older ones develop only small abscesses, unless a

large number of bacilli be injected directly into the circulation. Frogs and tree toads are resistant at medium, and susceptible at higher temperatures. Fowls resist anthrax ordinarily, but if they become chilled they rapidly succumb to it. Pigeons resist it save when semi-starved.<sup>5</sup>

It is noteworthy in this connection that the tetanus germ is inoperative save when inoculated simultaneously with foreign material, such as splinters of wood, dirt and pus. How familiar the foregoing facts sound to the student of a quarter of a century ago. Age, exposure, innutrition—lowered resistancy—special conditions, as invitations to contagion. Really, specific science has not yet done away with old-fashioned things. The pneumococcus is the specific microbe of pneumonia, but for some reason it often demands a chilling of the cutaneous surface in order to flourish and wax fat in the lung. In genito-urinary infections of a low grade, circulatory disturbances, internal blood metastasis, or traumatism is necessary to virulent development. Note, for example, cysto-pyelitis from sudden relief of prolonged retention, exposure to cold, shock, or operation trauma. Here indeed is food for thought. How unfortunate that we can not duplicate in the laboratory the conditions natural to the germ. How much more modest should be the claims of modern bacteriology. The accurate laboratory observation of to-day is a *sine qua non* of medical philosophy. Medical philosophy, both past and present, should be the foundation on which to build the material research of the present.

Anent the specificity of pathogenic organisms, it is of interest to note the evidence of evolutionary adaptation shown in the susceptibility of some animals to organisms to which other species are absolutely resistant. A point which throws the specificity of micro-organisms within at least the shadow of a doubt, is the fact that large quantities of harmless bacteria injected into the mammalian circulation may prove fatal because of the dead bacterial proteid contaminating the blood. Dead cultures of bacillus prodigiosus, or of the hay bacillus, are as certainly fatal as dead cultures of disease germs, and often as surely fatal as cultures of living pathogenic organisms. This observation throws much light on the relation of micro-organisms to disease and shows how narrow the specific influence of germs may be when dissociated from the effects of their metabolic products and dead and dying proteid. This point alone shows how broadly infection should be studied if it would be understood.

One of the most fascinating micro-organisms for study along evolutionary lines is the bacterium coli commune. The precise relation of the colon bacillus to the bacillus typhosus of Koch and Eberth is a matter of wide difference of opinion. The differences between the colon and typhoid bacillus are by no means irreconcilable on the score of evolutionary changes in what, by your leave, I will term the normal germ—the colon bacillus. Whether this germ is, as some believe, an oeco-parasite which, under as yet undetermined favoring conditions, acquires the ability to invade the animal body and there become transformed into the bacillus typhosus may be open to question, but the theory is at least rational enough along evolutionary lines. What is really known of the ubiquitous colon bacillus would lead one to expect even more remarkable performances from it. That this germ is normal to the intestine is tolerably certain; that it was always normal is less so.

\* Lecture delivered by invitation before the Buffalo Academy of Medicine, Jan. 21, 1902, and Creighton Medical College, Omaha, Neb., March 5, 1902.

The bacterium *coli commune* as it exists at the present day may be an evolutionary descendant of some organism which was distinctly pathogenic—perhaps akin to the *bacillus typhosus* as we know it. On this hypothesis the pathogenic properties of the germ as we observe them, and its possible transformation into the typhoid germ, would be rationally explicable on atavistic grounds. The versatility of this normally non-pathogenic micro-organism is marvelous. In the first place it is not only harmless when its environment is undisturbed, but apparently has a physiologic function to perform. The relief of chronic constipation by the administration of a pure culture of the colon bacillus is strongly suggestive in this direction. From a harmless intestinal saprophyte our colon bacillus may change into an organism which produces lactic acid fermentation in sugar and forms a brown pigment on potato. Considering the versatility of the colon bacillus one might not be far astray in inferring that the normal urethro-coccus has somewhat similar properties of adaptation and variation. Such indeed is my own belief.

The instances of micro-organic transformation observed experimentally are quite numerous, but a few of the most familiar examples are all that is required to illustrate the principle. The *bacillus anthracis* has been converted into a harmless putrefactive organism. Pasteur in his early experiments showed what could be done, first, with chicken cholera, and, secondly, with practically all disease germs by culture. He was able to play upon the virulency of micro-organisms with astonishing results; the range of effects varying from *nil* to extreme toxicity. Strange though it may seem, the profession at large did not grasp the meaning of Pasteur's results. A great biologic law had been established by him. Pasteur had neither added to nor subtracted from the phenomena of nature. He had given us merely a feeble imitation of what nature accomplishes under conditions which mortal man has not yet succeeded in producing.

Not only have disease germs been transformed experimentally; the bacteria of butyric acid, lactic acid, and pigment bacteria have been similarly modified. Both diminution and increase of the pathogenic, putrefactive, fermentive and pigment-forming powers of bacteria have also been shown to occur under natural, i. e., non-experimental and spontaneous conditions. The action of bacteria is constant only so long as their environment is the same. A very significant observation is the discovery of virulent Klebs-Löffler bacilli in healthy persons as oeco-parasites which may under favoring conditions produce diphtheria by either auto- or hetero-infection. Virulent diphtheria germs lose their virulency by culture and become saprophytic. It has been claimed by Roux, Frankel and others that the non-virulent diphtheria germs found in healthy throats are merely true diphtheria germs "which have lost their virulency." Had these investigators said, "which have not yet evolved to the phase of virulency," they might have been nearer the truth, although the view expressed by them solves a part of the problem.

It seems to me that the conflicting observations on diphtheria germs should command caution, at least. How much would one be justified in swearing on the witness stand? The observations of oeco-parasitic diphtheria germs and the observations of Roux, Frankel, Hueppe and others are alone sufficient to discredit any dogmatism in diagnosis. The study of the numerous and varying observations of diphtheria and its congeners has some bearing upon the possible origin of the gono-

coccus. It requires no wild flight of the imagination to conceive that the urethro-coccus bears the same relation to the gonococcus that Roux and Frankel claim for the Klebs-Löffler bacillus, the pseudo-diphtheria bacillus, and the oeco-diphtheria parasite.

The *bacillus tuberculosis*, Koch's pet specific micro-organism, has more of those properties which we are wont to term specific than most germs. Even the differences between the germ of fowl and that of mammalian tuberculosis appear at first sight distinctive. Hueppe and Fischel, however, by varying culture conditions so modified the mammalian germ that it grew like that of fowls, and vice versa. *Pari passu* with this transformation in growth property, an interchangeability of virulency developed, and the fowl became susceptible to the mammalian germ, and vice versa. Koch's latest dictum regarding the independence of bovine and human tuberculosis may be shown to be most vulnerable along these lines. Evolutionary adaptation and nutritional modification must needs differentiate human and bovine tuberculosis, but this does not militate against their interchangeability through atavism or otherwise. Least of all does it disprove their community of origin. In the study of germs we are ever confronted by fundamental evolutionary law, not in part, but as a whole. Tuberculosis is no exception to the rule. The same law of progression has affected both parasite and host. Both are so individualized that the species remain distinct.

I will admit that, as Theobald Smith has shown, the qualities of pathogenesis displayed by human and avian tuberculosis vary widely, but this is to be expected. The human being and the fowl bear the same comparative relations to the germ as do different culture media to any given pathogenic germ in the laboratory. The variation of virulency incidental to the passage of a given germ through different animal species—a most familiar experiment—bears eloquent testimony for the evolutionary theory of infectious diseases. The animal body modifies the germ just as all other environments do. The relatively high temperature of fowls as compared with mammals necessitates adaptation changes when the tuberculosis of the one is inoculated upon the other, and is alone sufficient to explain a spontaneous variation in type. McFarland<sup>6</sup> has made some interesting observations bearing on germ adaptation in general. He says: "The flagellate bacteria have a greater number of representatives among those whose lives are spent in water and in fermenting and decaying materials than among those inhabiting the bodies of animals. It may be added that parasitic disease producing bacteria which do not habitually gain access to the tissues but inhabit the intestines—such as the *bacillus* of typhoid—are actively mobile like the saprophytes, while those habitually entering the tissues and multiplying there are motionless and without flagella." The so-called facultative parasites and saprophytes, which possess the power of so adapting themselves to their environment that they can become either saprophytic or parasitic—warring indifferently with the living or the dead as best suits their ends and needs—show adaptation to environment and are sufficient alone to establish a principle.

It is a noteworthy fact of evolutionary suggestiveness that the relation between bovine and human tuberculosis is closer than either fowl and human or fowl and bovine. Koch said long ago on this point that fowl tuberculosis is hardly to be considered as a factor in the etiology of human tuberculosis. He is now of similar

6. Bacteriology, McFarland.

opinion as to the relations of bovine and human tuberculosis. Nocard, Fischer and Hueppe, however, have shown the bovine to be transformable under proper conditions into the human variety and vice versa. No matter what clinical differences may exist between fowl, human and bovine tuberculosis, their co-relation is hardly open to controversy, and, when viewed from the evolutionary standpoint, prophylactic negligence based upon Koch's dogmatic position is fraught with ultimate danger. We should deal not only with the germ but with his ancestry and entire kin. Our warfare against pathogenic germs should be patterned after the Kentucky feud, in which fine distinctions of relationship are not usually drawn.

Not the least important of the germs that show experimentally inconstancy and a versatility explicable only on evolutionary grounds are the cholera bacillus, which forms a yellow or brown pigment on potato and causes acid fermentation in saccharin solutions, the germ of glanders, forming brown pigment on potato, and the micrococcus pyogenes aureus, producing acid fermentation in sugar and a rich yellow pigment in cultures. Such observations are sufficient alone to upset Cohn's arbitrary classification of germs into pathogenic, chromogenic and zymogenic.

The practical side of the evolutionary view of bacterial life is obvious. Slowly but surely we are drifting from the untenable ground of unvarying specific entity to the safer belief that the soil in which the disease germs are sown and the conditions surrounding them are all important. In surgery, especially, we have learned the lesson that absolute non-infection of wounds is almost, if not quite impossible. When an environment unfavorable to germ development is provided, relative asepsis is secured. The tissues dispose of a greater or less quantity of more or less virulent germs if the latter have nothing to feed upon. *Mann ist, was er isst*. So, too, with the parasite that feeds upon him. Man is to the germ as macrocosm to microcosm.

The germ as the *causa prima* of disease can not well stand. Von Liebig was not so far wrong when, in his criticism of Pasteur's views of bacteria as the cause of fermentation and disease, he said, "One can not see causes."

It gives me great pleasure to reiterate to-night what, in substance, I said nearly twenty years ago, on the relations of bacteria to disease. As I expressed it then, "The tendency of modern research has been to seek for a specifically constant germ to fit a specifically constant disease, and then for a specific remedy to kill the germ." The etiology of disease will never be placed upon a secure foundation until the causes of the transformation of innocuous into pathogenic micro-organisms have been found. These conditions having been found, it will then be incumbent upon the scientist to determine the conditions under which the germ, once become pathogenic, best thrives and presents its most virulent properties, and vice versa. Less microscopic dogmatism and more biologic reflection is necessary. So far as the infectious diseases are concerned, the scientific light of the future must, it seems to me, be reflected along these lines. The trend is certainly in this direction at present. To this modern trend are we indebted for our serum-therapy, which is in effect a revival of old-time theory and practice.

With proper facilities for study, the venereal diseases should be models of accessibility for such research as I have suggested. Once understood, they would assist us in elucidating many important problems involving

other infectious diseases. With all due respect to the modern school of pathologists, I venture the opinion that we are still in the period of venereal confusion so far as etiology and pathology are concerned. True, we now have the one venereal disease of the great John Hunter resolved into three. We have even captured the gonococcus, but I venture to assert that we are not much nearer the primal causes than we were before. Indeed, I suspect we are further away, for in direct ratio to the assiduity with which we pursue specificity in germs, will be our departure from those lines of true scientific study of gonorrhea by making the ultra-enthusiastic advocates of the germ self-sufficient. With them it was not necessary to go further. The gonococcus has been a veritable venereal *pons asinorum* to some, with whom it causes all and to whom it explains all. I wish to record the opinion here that the true etiology of gonorrhea lies behind the gonococcus. Some of the profession have even begun to lose faith in the ubiquitous gonococcus in his own peculiar field—arbitrary diagnosis. It has come to pass that those who go beyond "the optic sharp I ween which sees things that are not to be seen" are rather skeptical about the ordinary office diagnosis of gonococci. As time goes on the gonococcus will grow less and less important and the conditions governing the evolution of the germ, and especially the evolution of virulent properties in primordially innocuous germs, will be known and will comprise the etiology of gonorrhea. I hope that some of us at least may live to see the realization of this prophesy. What has been said of gonorrhea applies with equal force to chancreoid, save in that a definite germ in this disease has not yet been established, but all of us have observed clinically wide variations of results of local venereal infection, embracing as it does all grades of inflammation and tissue change from a simple urethritis or simple balanitis on the one hand to a virulent chancreoid or gonorrhea upon the other. Giving due credit to the element of germ infection, observe how its importance is minimized by environmental influences.

It is my firm belief that gonorrhea and chancreoid develop *de novo* in the medium afforded by the secretions of the unclean and pathologically contaminated vagina. This development depends upon adaptation changes in innocuous or comparatively non-virulent germs—a spontaneous culture modification. The virulency of the resulting germ production is modified by many conditions, of which the following are most important: 1. Much depends upon the stage of decomposition of the vaginal fluids. The age of the process of germ development is all important. 2. The frequency of coitus. 3. The constitution and habits of the woman. 4. The character of any seminal or other discharge from the male which may be deposited in the vagina. 5. The degree of uncleanness of the woman.

Once elaborated and hetero-inoculated upon susceptible soil the results depend upon: 1. The amount and degree of virulence of the infectious germs and their products deposited upon an atrium of infection. 2. The cleanliness, local and constitutional condition, habits and sexual hygiene of the new host. 3. Individual predisposition. This involves individual immunity on the one hand and a tendency to inflammation, suppuration, serpiginous ulceration, phagedena, or gangrene on the other.

It would be beyond the scope of this lecture to reiterate all the points brought out in my earlier papers anent the clinical evidences in favor of the views therein expounded. I will therefore content myself by mention-

ing a few points that are familiar to all of you, with certain qualifications which I believe to be consistent with the views expressed in this paper.

1. The discharge from urethritis—the virulent form especially—if confined by a tight prepuce causes varying grades of inflammation and infection from slight balanoposthitis to destructive ulceration, and even suppurative bubo. The pus from both the sub-preputial process and the resulting bubo may be auto-inoculable, producing ulcers which, if not identical with—and the microscope does not as yet help us here—are clinically similar to chaneroid. This is especially true if auto- or hetero-inoculated upon cachectic subjects.

2. The long-continued contact of these sub-preputial secretions causes papillary over-growths—venereal warts and indurating edemas. The discharges of pregnancy, syphilitic lesions, gonorrhea and chaneroid produce similar results.

3. Chaneroid of the urethra is attended by urethritis of greater or less severity, not typically gonococcal always, it is true, but often so, and then attributed to double infection.

4. Gonorrhea and chaneroid are often associated in the same patient under circumstances which are suggestive of the contraction of the one disease from the secretions of the other.

5. Gonorrhea and chaneroid are contracted most often from the same class of women—often from the same woman. The higher class prostitute very rarely infects with chaneroid and exceptionally imparts gonorrhea.

Women who have infected numerous men with gonorrhea and chaneroid, singly or combined, are often found upon examination to have neither disease, so far as our present means of research enable us to determine. They are usually unclean, however. Such women are often merely media for infection, it is true, but this can hardly explain all cases. Latent infection explains some, but it is questionable if it explains everything save mediate infection.

7. Suppurative adenitis is common to all genital lesions, be they specific or simple. That the everyday explanation of this fact is mixed infection I am well aware.

8. It is often a very difficult matter to determine where simple genital ulcer ends and chaneroid begins. The test of auto-inoculation is hardly fair, as it is a test merely of the degree of virulence of the secretion. Auto-inoculation does not succeed in the later stages of chaneroid, and the results in any given case vary in virulence.

9. The natural tendency of chaneroid is to lose its specificity after a time and assume the character of simple ulcer. Boeck's fatuous method of so-called syphilization demonstrated this point beautifully. A similar and more marked evolution and involution should occur spontaneously under natural conditions. I maintain that this spontaneous change in chaneroid proves the position I have assumed regarding the evolution of the disease. The involution of the disease necessarily represents an antecedent evolution. If this be not true then the entire scheme of evolution falls to the ground. If evolutionary adaptation did not control infection, the comparatively benign infections would be malignant and fatal. The difference between benign and malignant germ infection simply is in great measure that mutual adaptation is a success in the case of the germ and cell in the one instance and a failure in the other.

There are many puzzling clinical facts bearing upon gonorrhea, which should inspire us with caution in diagnosis. In a number of instances in which patients have

been said to have deep-seated gonorrhea with gonococcal semen, I have been able to prove the non-specificity of the apparently typical gonococcus by culture and inoculation. In one case the gonococcus had been found in the semen by no less than seven competent men. The explanation in this case is a purely evolutionary one. The gonococcus had been shorn by adaptation of all its pathogenic properties, whilst retaining its physical characteristics. The final product, however, might, if deposited on suitable—i. e., filthy—soil, again evolve into a specifically pathogenic microbe.

It is noteworthy that a man with latent gonorrhea may infect his wife with typical pelvic infection. Inter-course being renewed later, the wife imparts to the husband a typical, virulent gonococcal urethritis. Here is a very striking illustration of germ adaptation. Another pertinent fact is that women with latent gonorrhea, or recently infected by active gonococci, may have no symptoms until the onset of the menstrual period. Coincidentally with the change in soil due to congestion of the sexual tract, acute infection occurs. This is an important germ evolutionary evidence.

A thorough and radical change in scientific thought and research method must occur before such views as I have expressed in this paper can be established on a sound basis, and, so long as our present cut-and-dried methods of laboratory research prevail, not one step will be taken in the right direction. The "circle" of Koch was a vicious circle indeed. No student's examination has been complete without a knowledge of it, yet I venture to assert that it has done almost as much to retard true scientific research as it has to further it. Its range of application has been so narrow as to emasculate it, yet has it dominated pathologic research. Its several test points have failed in numerous kinds of indubitably specific disease. It has been found that the old view of special susceptibility to disease and of a *locus minoris resistentiae*—which we had all but thrown in the waste basket—must needs be revamped for modern etiologic necessities. As already outlined, it has been found that not all so-called specific microbes are susceptible of pure culture. Some germs have been shown to be inactive pathogenically save when mixed with other germs. Germs which are ordinarily innocuous have been found to become pathogenic under certain special conditions. Most disease germs are effective through the poisons they create, and not of themselves.

I reiterate these points merely to emphasize the fact that the germ is not only not all, but is a small part of what we must learn of etiology and pathology. In conclusion, I will state it as my belief that the etiology and pathology of infectious diseases of the future will stand, not upon the germ but upon the myriad of conditions yet unknown that lie behind the germ. The germ bears the same relation to the true etiology of disease that the cosmogony of Moses does to the universe. It crudely attempts to explain but a small part of a great whole.

## Clinical Reports.

### ACUTE CHOREA. RECOVERY.

CHARLES S. WALKER, M.D.  
CONCORD, N. H.

F. O. B., male, aged 31, single, with no particular occupation, but having worked in a wood planing-mill in Massachusetts, entered the New Hampshire State Hospital, Concord, N. H.,

Oct. 9, 1901. He had not been well for four weeks. In the history of the case it was intimated that he had been a little odd since childhood—not quite as adept a scholar as some of his chums. His family medical attendant said the only severe illness that the patient had ever had was enteric fever, 15 years ago, from which he made a perfect recovery.

*Physical examination* showed height, 5 ft. 6 $\frac{3}{4}$  in.; weight 122 pounds; poorly nourished; pulse 68; tongue slightly coated; complexion pale; pupils somewhat dilated, but equally, reflexes normal. There was a peculiar dragging to left leg on walking, which was said to be congenital. It is said that his mother, while pregnant, was frightened by a man who had just such a gait. The reflexes of skin and abdomen were absent; cremasteric, delayed but present; tendon, right, exaggerated; knee-jerk, left, absent; wrist and biceps, absent. Bodily symmetry was fairly good, lungs normal, heart somewhat enlarged, murmur heard at the apex—mitral regurgitant—clearly heard at angle of scapula on left side of back, and the abdominal organs were in normal condition.

*Psychic Condition.*—There is no history of nervous disorder, insanity or tuberculosis in the family. The patient's habits have always been good, and his conduct well behaved; in temperament he is slightly nervous, and somewhat agitated, and his expression is anxious. Attention and memory were good, both in regard to past and present affairs. His ideas were somewhat retarded, but not to a noticeable extent. He had no delusions, hallucinations or illusions. Before his admission he was at home for a short time and was troublesome. His parents were afraid of him as they had never seen him in this condition. He was ransacking around the house generally, overturning chairs, tables and other articles of furniture, so it was deemed expedient to send him here.

*On admission* the patient was placed in bed. He was very nervous, moving and twisting around continually, looking first in one direction, then in another. Says he feels perfectly well, but is unable to keep quiet. When eating, crumbles up his food and amuses himself by making a line of crumbs around the edge of his bedspread. Sleeps fairly well. There is a good deal of involuntary muscular twitching, seen perhaps more clearly in the left hand than elsewhere.

*October 22.*—The patient continues to be very nervous, going through all kinds of antics or choreiform movements with his hands and feet, first lying down and then suddenly sitting up, then lying down will go to sleep for a time. These movements are more definitely manifested in the left hand, although the right is involved. When awake he can not control these movements, the fingers being continually in a state of agitation. After lying in bed for a few days he was allowed to dress and sit up, but being restless was returned to bed. When lying perfectly quiet the muscular twitchings were plainly visible over different parts of the body. He has been eating very well. While taking his food he does considerable juggling with his knife, fork and dishes, and makes all sorts of grimaces. He shows a little improvement.

*November 4.*—The patient is now able to lie perfectly quiet and manifests no choreiform movements except occasionally when a little excited. A few days ago it was impossible to keep his bed made up. He now keeps the same in splendid order.

*November 8.*—The fingers can be controlled perfectly—no movements over any part of the body. He is looking fine physically, is gaining fast, and has shown wonderful improvement.

*December 10.*—He was allowed to attend the dances, but the excitement and music were more than his nervous condition would admit, so he desisted from this pleasure. He has taken outdoor exercise and enjoys it very much.

*Conclusion.*—The patient made a splendid recovery after an illness of 12 weeks.

*Treatment.*—After admission a tonic was prescribed—nucis vomica, m. 10; tinct. gentian co. 3l. t. i. d.—which was administered for a few days. On October 22 this was discontinued and Fowler's solution was given with 5 drops as the initial dose t. i. d.; this was increased by one drop daily until the dose was

15 drops t. i. d. There were no symptoms of arsenical poisoning. From this point, a decrease was made until 10 drops were reached. Then the solution was discontinued. No other medicinal agents were used except an occasional laxative to keep the bowels in good order.

The food was plain and nutritious, a goodly amount of milk being taken, but very little meat eaten. Eggs in the form of eggnog were freely administered. After convalescence was established, liberal quantities of good New Hampshire air was indulged in.

The rapid recovery of this case shows that Fowler's solution, judiciously used, with rest, quiet and a light nutritious diet, is an excellent treatment in cases of acute chorea.

## TWO CASES OF PERIPHERAL GANGRENE ASSOCIATED WITH LOCALIZED DIS- EASE OF THE ARTERIES.

HARRY M. SHERMAN, A.M., M.D.

AND

THOMAS W. HUNTINGTON, M.D.

PROFESSORS OF SURGERY IN THE UNIVERSITY OF CALIFORNIA,

SAN FRANCISCO, CAL.

### HISTORY OF CASE ONE.

*CASE I.*—By Dr. Sherman. The patient is a man aged about 40. He has had no serious illness since childhood, when he had an attack of scarlatina, following which he was unable to walk for four months. He has not had syphilis. He has some dry eczema upon his forehead and about the joints. He eats well. His bowel and bladder functions are normal and he sleeps well. He has no sugar nor albumin in his urine.

He gives a long account of the conditions which led to the removal of his left leg. About 1878, when it was the fashion to wear low shoes with large buckles, he had a severe pain at the top of the left instep and so discarded his buckle shoes. For some time he was then free from pain, but after awhile it returned with greater severity; it was thought to be rheumatism and for this he was treated. For seven years he had this pain, with intermissions; but the intermissions became shorter and fewer and the pain, when present, became more severe. Apart from this pain his health was good.

In October, 1896, he was suffering greatly and at that time he thought he had an ingrowing big toenail. He was treated by a chiropodist, and the result was a wound which would not heal, but became septic and finally necessitated the amputation of the big toe. The stump, however, did not heal and the local and general septic condition became worse. An incision was made on the dorsum of the foot; this partly controlled matters, in that the general symptoms subsided, but the local condition continued and he lost all the other toes, except his little toe. There was a pause here, but not for long. In April, 1897, an ulcer appeared upon the instep; this ulcer would not heal and it was decided to curette it. This little operation disclosed such fragile bone and this condition was found to be so extensive, that an amputation was done five inches above the ankle. This stump also did badly and two months after the amputation quite a sequestrum was discharged, and later, when the soft tissues contracted, the bone protruded and another amputation became necessary, four more inches of the leg being removed. This stump followed the course of the others; an ulcer persisted which would not heal under any treatment until hot-air baths were tried: under them it nearly closed so that an artificial leg could be worn.

The patient then went to Nome. His stump became worse and his right foot began to pain him, there being a sensation of intense cold in the sole. This was persistent and irremediable and he returned to California. Here he began the hot-air baths for his stump and the ulcer fully healed; but the right foot became worse, pain being complained of in the sole and instep. For these pains an insole was put in the shoe to support the instep, but without relief. At this time he got a small corn on the little toe and treated it himself. This

resulted in an ulcer, for which Dr. Lewitt was called in: he instituted treatment to secure its healing, but it would not heal. At this time I saw him and agreed in the removal of the distal phalanx: this made matters worse, pus burrowed into the sole, red swollen areas developed in the dorsum and there was danger that the local sepsis would become more and more extensive. Dr. Lewitt transferred the case to me, the patient went to St. Luke's Hospital and under anesthesia both the sole and dorsum of the foot were laid open. The incision through the sole disclosed only a suppurating tract. That through the dorsum exposed dark congested areolar tissue, which looked as if it were ecchymotic, though there was no effused blood. This operation had exactly the same result as all the others. Matters were made distinctly worse and the edges of the incision became gangrenous. I amputated the leg at the junction of the upper and middle thirds. At the request of the artificial leg manufacturer, I made antero-posterior flaps, and these were made very long to permit of a possible marginal gangrene and its separation, and leaving still enough flap tissue to cover the bone. The flaps bled properly, but it was noticeable that no hemorrhage came from the anterior tibial artery. In general, the tissues of the stump looked darker than they should and the blood from them was also darker than normal. The stump was closed by tiers of sutures, uniting individual tissues, periosteum to periosteum, muscle to muscle, and so on, with, finally, a subcuticular suture in the skin. A small gauze wick was placed in the middle, reaching to the periosteal suture. The gauze was removed after 48 hours and the stump looked well. At a second dressing, 48 hours after the first, an area of redness was evident, triangular in shape, its base corresponding to the edge of the middle of the anterior flap and its vertical height being about 3 cm.: at the subsequent dressing, two or three days later, it had disappeared. From that time, healing proceeded uneventfully but slowly, though quite a crease formed in the anterior flap in the site of the reddened triangle. About ten days later this crease unfolded, the place became prominent, dark and fluctuant. With this was some pain. A puncture released some bloody serum. The swelling disappeared, the normal color of the skin returned and the little wound is apparently satisfactorily healed.

Six months later: There has been a further destructive process in the stump at the site of the red triangle, and the artificial leg, which had been fitted, has had to be put aside. This is in keeping with the report of Dr. Taylor, which shows that the disease in the arteries extends above the level of the amputation.

#### HISTORY OF CASE 2.

CASE 2.—By Dr. Huntington. The patient is a man of 32, a worker in leather. His family history was negative. He presents no history of syphilis or alcoholism. There is a history of an indefinite trouble in his right instep 15 years ago: the instep was painful and tender to the touch. The surface was cold and perspiration was excessive. He states that ever since that time he has suffered from cold feet.

On Jan. 4, 1901, he was admitted to the French Hospital, complaining of severe pain in the right great toe. Upon admission, the attending surgeon found a small, black area upon the outer side of the toe. The nail was removed. Three days later, he entered the City and County Hospital: upon his admission the entire toe was found to be gangrenous and was removed by disarticulation at the metatarsophalangeal joint. Two days later the dorsum of the foot became gangrenous. The gangrene slowly spread. It was of the moist variety and though very indolent there was no attempt to form a line of demarcation. The general condition of the patient was bad.

Three weeks later he was removed to the Mt. Zion Hospital, at which time the leg was amputated in the middle third. A small portion of the anterior flap sloughed, but ultimately the patient made an excellent recovery. A few weeks later a small ulcer appeared in the scar, on the inner side of the stump. This ulcer has never healed and prevents the use of an artificial limb. The stump is cold, perspires freely and is poorly nourished.

At this date, the process appears to be beginning in the left foot and leg. The leg is cold, there are upon the foot discolored areas which are sensitive to pressure. The muscles of the leg are flabby and the leg tires easily.

#### PATHOLOGY OF THE CASES.

The two legs amputated were examined by Dr. A. E. Taylor. Since no alterations, apart from the areas of gangrene, were found in the muscles or nerves, the vessels alone will be described.

On receipt of the specimens, dissections of the anterior and posterior vessels were done. It was noted, particularly for the anterior vessels, that they were surrounded by an abnormal amount of connective tissue, which was very dense and quite unlike the normal areolar tissue usually found about the vessels. The vessels were then measured and fixed. Thrombosis was noted in both anterior tibial vessels, in both anterior veins and their subdivisions and in the posterior veins in the case of Dr. Huntington.

The measurements of the arteries in the middle thirds were confirmed by measurements in sections with the object-mikrometer of Zeiss. Since the measurements for the total width of the vessels agreed in general with the measurements made of the fresh vessels, it is assumed that the internal measurements likewise were the same. The measurements given are therefore the microscopic measurements.

|                                    | Total Diameter.<br>Mm. | Each Wall.<br>Mm. | Lumen.<br>Mm. | Area of Lumen.<br>Sq. mm. |
|------------------------------------|------------------------|-------------------|---------------|---------------------------|
| Normal tibial, ant. . . . .        | 3 to 4                 |                   |               |                           |

| Case 1.—T. Ant. . . . .            | 1.31                   | 0.305             | 0.7           | 0.41                      |
| Case 1.—T. Ant., lower 3d. . . . . | 1.09                   | 0.275             | 0.54          | 0.23                      |
| Case 1.—Ant. T. . . . .            | 0.635                  | 0.2               | 0.235         | 0.04                      |
| Case 1.—T. Post. . . . .           | 1.35                   | 0.38              | 0.6           | 0.28                      |
| Case 2.—T. Post. . . . .           | 2.06                   | 0.725             | 0.61          | 0.28                      |

As compared to the normal, these arteries display a great reduction in the total diameter and a normal thickness of the wall with a great reduction in the diameter of the lumen. Normal arteries of the same total diameter as these would have much thinner walls, so that these walls, though apparently normal, are really increased in thickness. The functional result is best illustrated by the figures for the areas of the lumens: in no case is the square area in a diseased vessel as much as one-tenth the normal area, while in the anterior tibial vessel in the case of Huntington it is but one one-hundredth. Whether these reductions in the general lumen and diameter occurred before or after the thrombosis can not be said: the posterior tibial in Sherman's case, which was patulous, presented the same marked reductions and this suggests that the reductions antedated the thrombosis.

On microscopic section of the vessels, the elastic tissue and the muscular coat seem qualitatively normal. In particular the normal appearance of the media is in marked contrast to the conditions in arteriosclerosis. Both the muscularis and the elastic tissue seemed rather in excess quantitatively. The intima was not notably thickened in either case, except in the areas of thrombosis, where the intima was involved in the process of obliterative fibrosis. No signs of lime salts could be found. The endothelial cells lining the vessels were normal in the patulous portions. The adventitia was thickened, but was usually well outlined from the surrounding excessive fibrous tissue. In the areas of thrombosis the process is an obliterative arteritis.

The portions of the vessels not submitted to microscopic section were dissected. The process of thrombosis did not extend along the entire length of the vessels involved, except in the case of the anterior artery in the case of Huntington; there were small portions in which the lumen was patulous. These portions were carefully examined with a hand-glass for areas of atheroma. None were found. The vessels were not at all tortuous, but perfectly smooth and straight.

The veins presented no other lesions than thrombosis. These veins vary much in thickness normally, and were not thicker than they often are in individuals in middle or advanced life.

SATURDAY, MAY 24, 1902.

## PROFESSOR VON LEYDEN.

Professor Ernest von Leyden of Berlin celebrated his 70th birthday on April 20 last. The occasion was taken as a suitable opportunity for felicitation by medical men all over the world. Professor von Leyden is one of the greatest of living practical clinicians and his contributions to internal medicine represent some of the most significant practical advances of the last thirty years. In many lines of medical practice his work and that of his clinic, from the time when he presided over the department of internal medicine at the small university of Königsberg nearly forty years ago, to his more than a quarter of a century at the Charité in Berlin, has been thoroughly representative of what is best in the progress of applied medicine and has proven a fruitful source of suggestion and inspiration to clinicians the world over. The Festschrift for his birthday, dedicated to Professor von Leyden by his many medical friends and pupils, has just reached this country. The two volumes constitute a very appropriate tribute to a great practitioner. Nearly every prominent authority in internal medicine on the Continent is represented by a contribution in the first volume. Articles from Professor von Leyden's pupils make up the second. These include such well-known men as Professor Salkowski of Berlin, Professor Eichhorst of Zurich, Professor Jaffe of Königsberg, and such successful investigators as Professors Brieger, Goldscheider, Bernhardt and Klemperer of Berlin. The table of contents of the volumes gives the best possible idea of the amplitude of von Leyden's influence.

As is very proper, most of the contributions to these volumes are clinical in character. Professor Gerhardt and Senator von Leyden's distinguished colleagues at the Charité have each a suggestive article. Professor Gerhardt calls attention to the frequency with which vascular nevi are associated with local hypertrophy of the part affected. He suggests a certain relationship between these anomalies and erythromelalgia and seems to hint that modification in the disfigurement that is so prominent a feature of nevi may be brought about by section of the nerve carrying the vasomotor fibers to the part. Professor Senator discusses, illuminatively, the significance of the so-called "perisystolic," or "prediastolic" heart murmur. The distinguished head of the clinic at Vienna, Professor Nothnagel, contributes a sketch of the career of his life-long friend and colleague, Professor von Leyden, whose assistant he was for many years. Professor von Schrötter of Vienna writes on actinomycosis of the lungs and heart.

Professor von Leyden's colleagues in Berlin are especially well represented. Professor Heubner reviews the clinical work of his department for the last eight years and says a last word on the vexed question of the connection between rheumatism and chorea. For him they are undoubtedly equivalents and nosologically related in their causes. Professor Jolly discusses head tetanus and facialis paralysis. Professor Ehrlich, so long of Berlin, now of Frankfort, has a most suggestive paper on the relations between chemical constitution, molecular arrangement and pharmacologic action. Professor Lazarus discusses the relations between adenoid vegetations and heart dilatation with weak action. Professor Wassermann reviews the important results of recent investigation on the effects of hemolysin, cytotoxin and precipitin.

The French clinicians are well represented: Bouchard and Marie of Paris, Courmont of Lyons, Bourget of Lausanne and Metchnikoff of Paris. The last-named has an article on an unexpectedly up-to-date subject— inflammations of the appendix. He calls attention to the fact that appendicitis is rare in China, but on the increase all over the rest of the world. He lays no little stress on the presence of various animal parasites in the intestine during early life as producing conditions that predispose to the development of inflammation of the appendix. Of the foreign clinicians, the Russians are best represented and this, it may be said, in spite of the fact that Professor von Leyden was summoned to attend the late Czar. Professor von Bechterew writes on the rhythmic tremors and automatic movements of the hysteric. Professor Kernig of present-day notoriety, because of the discussions over the Kernig symptom in meningitis, writes on the use of quinin in the treatment of typhoid fever, for which he has found the remedy of great value. Professor Minor of Moscow writes on hemispasm of the tongue and lips as a late symptom of organic hemiplegia that makes possible its differentiation from functional hemiparesis. Rome and Bucharest, Helsingfors and Budapest, Amsterdam and Copenhagen, London and Athens, all send their offering of reverence for long years of clinical work well done to the master at Berlin. The spirit behind the work is an earnest of that better fellowship among the men of all nations that is so manifest and so promising at the beginning of the twentieth century and that has especially drawn the members of the medical profession together. The fellow-feeling for suffering humanity that makes all physicians kin, will be an inspiration to that coördination of effort that crowns investigation with success. No better example of its helpfulness can be found than in the work of von Leyden, his pupils and his friends.

## THE MODERN FAMILY PHYSICIAN IN LARGE CITIES.

The passing of the old-style family physician in our large cities means a distinct loss to society unless he be replaced by another and more modern family medical adviser. The present vogue for treatment by specialists

and for office consultation is a natural outcome of prevailing tendencies in both professional and lay circles. People need not be particularly well-informed nowadays to have little faith in the ability of one individual to cover the whole field of either medicine or surgery. They realize, for instance, that he who thoroughly knows obstetrics probably is not justified in uttering a final word on diseases of the nervous system, or that good surgery for crooked feet is not to be expected of the gynecologist. The consequence is that the several members of one family may have different medical attendants, and perhaps even change from specialist to specialist as their ailments vary. Office practice fosters these tendencies. Altered conditions of living in cities, such as disappearance of the homestead idea in this generation of apartments and flats, and the frequent change of residence from one part of the city to another, among all classes often, except in the case of office consultations, means calling in a new physician.

Great disadvantages are apparent in these tendencies, though considerable allowance be made for the value of consulting directly with specialists. Many conditions of home life are elusive in a scientific office examination, which as truly make for pathologic conditions as any state of body function discoverable by laboratory methods. Novelists are fond of portraying the case of the young woman who with her ailments born of some love affair quite baffles the doctor's diagnostic skill. Henry James, a careful student of human affairs, although perhaps hardly a realist, makes a young maiden in one of his stories rapidly succumb from an amatory *faux pas*—leaving her physicians shaking their heads and pronouncing it a very curious case. As a matter of fact, in everyday life the family confidant, such as the family physician should be, is the only person to fairly understand many ailments which have for their base defective social surroundings or mental conditions.

An important rôle for the family physician wherein he can fulfill a great social need is in the practice of preventive medicine. Hygiene of the individual and of the household are of vital importance from every point of view, and no one can know the factors and solve the problems so well as a tactful and trusted family physician. The writer has seen an instance of a young child treated at an office regularly all one winter for a skin affection by a physician of experience who neither found a cause nor effected a cure. The matter being carefully studied into by a physician who saw the family at home, the cause was discovered to be exposure to the direct heat of the kitchen range during the morning bath. This proceeding stopped, the dermatitis quickly healed without treatment. Such unconscious and apparently trivial slips in hygiene are discoverable only by the family physician who has the advantage of intimate acquaintance with life in the home.

Much benefit accrues to the family having a trusted physician in the greater incentive to go to him with

small ailments. If these only occasionally turn out to be important, yet one occasion may justify by the results of early treatment the reporting of a great many inconsiderable ills. No better illustration of this is to be found than in the demand which gynecologists are recently making upon the family physician for early diagnosis of uterine carcinoma by the very symptoms which women do not think of enough importance to bring to the attention of a specialist.

The modern family physician need not presume to be all-knowing, but he must be especially well-informed in the general matters of surgery and medicine, and well enough equipped with common sense to coöperate with the specialist whenever there is any suggestion of need. Besides training in preventive medicine it will not be too much to demand that he know enough of the physiologic development of the nervous system to give advice about the early education of children, and enough of psychology to do what the occasional consultant can rarely do, namely, recognize and remedy if possible any factor in the patient's mental habits or environment which may be a causative agent in the pathologic condition.

#### INORGANIC FERMENTS.

By inorganic ferments is understood finely-divided metals (platinum, silver, gold, etc.) suspended in water as solutions. This fine division of the metal is obtained by passing a strong electric current from one bar of metal to another in pure water. It does not concern true solutions, however, because there is no change in the freezing-point, the vapor-tension, or the boiling-point of the fluid; neither does it not produce any osmotic pressure. For these reasons these mixtures are called pseudo-solutions or colloidal solutions; they are analogous to solutions of starch and albumin, but have also remarkable fermentative properties. Thus, a colloidal solution of platinum hastens the oxidation of alcohol into acetic acid; others invert cane sugar, etc. Like organic ferments, small amounts of colloidal solutions of metals effect large transformations without themselves undergoing any change. Such reactions are termed catalytic.

The work here referred to has been carried out by Bredig and his pupils, and it is from the reviews of their work by Harry C. Jones<sup>1</sup> that the facts cited are abstracted. It has been shown, further, that like organic enzymes, colloidal metals are exceedingly sensitive to certain substances, such as hydrocyanic acid, carbon bisulphate, etc., which interfere also with the fermentative action of finely-divided metals. Bredig and his co-workers have made qualitative and quantitative studies of the "poisonous" effect of such substances as those mentioned upon colloid platinum by investigation of its rate of decomposition of hydrogen dioxid after the addition of various poisons, using in all about thirty substances. From the effects of some of these poisons the platinum would

1. Bulletin of the Johns Hopkins Hospital, September, 1900, p. 224, and May, 1902, p. 97.

recover, e. g., hydrocyanic acid and cyanogen iodid, while the detrimental action of other substances, among them iodine, remained permanent. To cite only one actual example—a solution of hydrocyanic acid containing one gram molecular weight in two million liters reduces the reaction velocity of colloidal platinum one-half. The fact that the poisonous action after a time diminishes materially, i. e., the ferments "recover," is regarded as due to the oxidation of the hydrocyanic acid in the solution.

Comparative studies show that there is a general agreement between the action of poisons on organic and inorganic ferments. We can do no better than requote the following paragraphs from Bredig already cited by Jones: "All these facts point to an unmistakable analogy between the contact actions in the inorganic world, and the actions of ferments in the organic world. As in the case of my colloidal catalyzers, we are dealing with reactions in which enormously-developed surfaces are involved, so is it probable that the same condition obtains in the actions of ferments, enzymes, blood corpuscles, and oxidizing and catalyzing organic substances. We see, therefore, that the organism develops its enormous surfaces in the tissues and colloidal ferments not only because it requires osmotic processes, but on account of the very great catalytic activity of such surfaces. If, as Boltzmann says, the war for existence which living matter must wage is a war about free energy, certainly of all forms of free energy the free energy of surface is the most important for the organism." Bredig does not maintain that there is any mysterious identity between enzymes and the metals, but he thinks it is fair to regard the colloidal solutions of metals, in many relations at least, as inorganic models of organic enzymes. The value of Bredig's work for biology and medicine lies in the better understanding it gives us of the nature of ferment action which underlies so many of physiologic and pathologic processes.

#### THE VALUE OF BLOOD EXAMINATIONS IN THE DIFFERENTIATION OF TYPHOID AND MALARIAL FEVERS.

When typhoid and malarial fevers prevail coincidently, particularly when atypical forms of each occur, the diagnosis in a given case may be attended with the greatest difficulty and a correct decision may be possible only after invoking the aid of all refinements in physical exploration. A positive reaction with the serum agglutinating test on the one hand and the presence of the plasmodia in the blood on the other hand, together with other more or less characteristic symptoms, may leave no room for doubt, but occasionally these phenomena may for one reason or another be absent. It seems not impossible that the different infectious diseases are attended with more or less definite, perhaps specific, changes in the blood and the near future may yield additional diagnostic means of great precision and certainty.

We have already referred to the agglutinating test and the hematozoön of malaria. It is further known that in both typhoid and malarial fever when uncomplicated the

number of red and of white blood corpuscles and the percentage of hemoglobin are diminished. Recent observations seem to show that certain differences in these changes afford a means of differentiating typhoid and malarial fevers. In a series of some 50 cases of continued and remittent fevers observed in India among Europeans and natives, Dr. Leonard Rogers<sup>1</sup> found that a fairly close correspondence existed in cases of typhoid fever between the reduction in the number of red blood corpuscles and in the amount of hemoglobin, so that the color-value remained practically unchanged. The degree of anemia was comparatively slight, the depreciation rarely reaching as much as 50 per cent., while the white blood corpuscles seldom fell below 3000 and rarely below 2000 in the cubic millimeter. On the other hand, the degree of anemia was often greater in cases of malarial remittent fever, but the reduction in hemoglobin did not keep pace with that in the number of red corpuscles, so that the color-index was higher. In cases of malarial remittent fever with little or no anemia the reduction in the number of white blood corpuscles differed little from that noted in cases of typhoid fever, but in the presence of marked anemia the number was almost always much lower than is the rule for typhoid fever, counts of 2000 or less being not rare. Notwithstanding the reduction in the number of white blood corpuscles it was found that the proportion of mononuclear leucocytes was increased, the increase affecting the lymphocytes (up to 40 per cent. and more) in the case of typhoid fever and the large mononuclear cells (up to 12 per cent. and more) in the case of malarial fever.

Cells as large as the polymorphonuclear leucocytes or larger were considered in the latter group, while those smaller in size were placed in the former. Myelocytes were more commonly found and in larger number in cases of malaria (from 1 to 5 per cent.) than in those of typhoid fever, in which latter disease, further, the polymorphonuclear leucocytes were the more considerably reduced. Leucocytosis was rare in cases of malarial fever even when complicated, as, for instance, by broncho-pneumonia. The presence of leucocytosis could often be detected in stained preparations from the presence of an excessive number of polymorphonuclear leucocytes. The observations briefly summarized in the foregoing are exceedingly interesting and they may prove to be of great value. It is appreciated that their significance is not infallible or invariable, but, like that of other symptoms, is relative. In a word, the results of blood examinations must be estimated here as elsewhere in connection with the other conditions present.

#### THE MECHANISM OF THE LARYNGEAL PALSIES COMPLICATING TABES DORSALIS.

Occasionally there occurs in the course of tabes dorsalis paralysis of laryngeal muscles, especially late in the progress of cases attended with symptoms referable to the cerebral nerves. More rarely such a condition

1. British Medical Journal, April 5, 1902, p. 827.

appears as a premonitory manifestation, in advance of the typical symptoms, especially the ataxia. Two cases of this latter character have recently been reported by Dr. A. Cabn.<sup>1</sup> In one of these bilateral paralysis of the dilators of the larynx was observed soon after the development of rheumatoid pains, pupillary immobility and abolition of the knee-jerks. In the second case there were at first laryngeal crises, followed by the symptoms of paralysis of the posterior crico-arytenoids, tabetic arthropathies and pains and finally ataxia. A study of the cases of like character recorded in the literature shows that in the large majority alterations in the peripheral nerves supplying the muscles of the larynx are found exclusively. These changes may consist in isolated degeneration of the muscles or of the intramuscular nerve-elements or in degeneration of the recurrent laryngeal nerve alone or in degeneration of the recurrent laryngeal and of the trunk of the vagus in the neck or up to the medulla oblongata or finally into the medulla, with normal nuclei. Only a few cases with definite nuclear changes are known and in only one case has disease of the nucleus ambiguus been demonstrated. In all of these cases there was found also, whenever looked for, degenerative changes in the peripheral nerves, often more considerable and more important than the nuclear degeneration. The clinical picture in the cases in which changes were present in the peripheral nerves alone or in predominant degree exhibits a median position of the vocal bands. This may persist even when the paralysis and atrophy involve also other internal laryngeal muscles in addition to the posterior crico-arytenoid muscles. On the other hand, in the cases of nuclear atrophy the clinical picture is variable. The vocal band on one or both sides may be in the cadaveric position or in the median position and there may be derangement of sensibility.

#### IMPROVEMENTS IN THE TECHNIC OF AGGLUTINATION.

Undoubtedly one of the most potent reasons that certain laboratory methods of great advantage to the physician do not more rapidly find their way into actual practice is the complicated character of some of the manipulations. Every step towards the simplification of such methods is welcome. Take the agglutination reaction in typhoid fever, for instance. Its great diagnostic value is universally acknowledged; it is not a very difficult reaction to carry out; but it requires a fresh, pure culture of typhoid bacilli, and many practitioners no doubt find it burdensome to endeavor to keep such cultures on hand. Of course, cultures are always obtainable from laboratories, but then there is the transportation from day to day and the maintenance of an incubator at constant temperature. Unless the physician has had real laboratory training and is interested in keeping up a clinical laboratory of his own—and it seems that this is becoming more and more commonly the case, especially among the younger men—he naturally shrinks from adding a number of new details to his already full list of duties. And so it comes to pass that the patient gets well or dies with an indefinite diagnosis, but perhaps the more serious result is that the

physician falls behind and gradually slides into loose methods. It has recently been demonstrated that in place of living typhoid cultures of a certain age, formalized bouillon cultures may be used.<sup>1</sup> The method comes from Ehrlich's laboratory. Bouillon cultures of typhoid bacilli after growing one day at 37° C. are killed by the addition of one part formalin to 100 parts bouillon culture. Their mixture is allowed to stand for 48 hours at 37° C. when the supernatant homogeneous fluid is poured off. This fluid may be used for weeks as one of the factors in the agglutination test. It is best kept in the ice-box and should be well shaken before being used. The test may be made by adding the same quantity of the formalized bouillon to the same quantity of various dilutions in physiologic salt solution of the serum to be tested, using for this purpose small glass cellars such as are employed in histologic work. Agglutination is characterized by the formation of crumbling, stellate masses easily seen under a low power and weak illumination. It would seem that this use of formalin bouillon would simplify the test considerably, and for that reason it may find favor with the progressive practitioner.

#### CATARRHAL INFLAMMATION OF THE MIDDLE-EAR AS A FACTOR IN THE PRODUCTION OF FACIAL PALSY.

It is probable that the influence of cold as a cause of disease has been greatly overestimated. Unless the reduction in temperature be sufficient to interfere with the vitality of the part or to prevent reaction, it seems more likely that it acts merely as a contributory factor, possibly favoring the activity of pathogenic micro-organisms almost always present. Perhaps also the cold has some influence upon local as well as upon general metabolism, but whatever the explanation, there seems to be no doubt that exposure to cold in some way favors the development of a not inconsiderable number of morbid conditions. Conspicuous among these are inflammations of nerves, and here we have a striking example in facial neuritis, the palsy resulting from which is the most common form of paralysis due to disease of a single nerve and for which cold is held responsible in about three-quarters of the cases. Now, in explanation of the mechanism through which this result is brought about, Dr. H. O. Reik<sup>2</sup> suggests that, in a considerable number of the cases at least, there results an acute or subacute inflammation of the middle ear as an intermediary condition between the exposure to cold and the appearance of the paresis. He reasons that inasmuch as the sheath of the facial nerve is not uncommonly in direct contact with the mucous membrane of the middle ear or separated from it only by a thin lamella of bone, the nerve may suffer in consequence of a catarrhal condition of the ear resulting from exposure to cold, and he suggests that in some if not many cases of facial palsy symptoms of coryza or pharyngitis, followed by pricking or stinging in the ear, with a sense of fulness and tinnitus and deafness, will, if looked for, be observed in advance of the muscular weakness. In support of this view an illustrative instance is reported and reference is made to three others, and significance is attached to

1. *Deutsches Archiv für klinische Medizin*, 73, B., p. 281.

1. *Prücher Centralbl. f. Bakt.*, 1902, xxxi, 400-403.

2. *Bulletin of the Johns Hopkins Hospital*, April, 1902, p. 83.

the rapidity with which often recovery takes place and to the further fact that the most appropriate treatment, namely, leeching, counter-irritation, purgation and iodids, is equally applicable to both conditions. Finally, the recommendation is made that in order to hasten recovery paracentesis of the tympanic cavity should be practiced if examination discloses the presence of an exudate. While facial paralysis is not a dangerous disorder it is disfiguring and undesirable and it should, whenever possible, be prevented or relieved. In a not inconsiderable number of cases it persists for a long time and not rarely it may leave permanent deficiency, so that any means that is calculated to contribute to its prevention and to hasten its disappearance should be most heartily welcomed.

#### TUBERCULOSIS OF THE STOMACH.

Tuberculosis of the stomach is an exceedingly rare form of tuberculous as compared with the frequency of tuberculous localization lower down in the intestinal tract. The causes of this relative immunity to tuberculosis on part of the stomach are not altogether clear. Several investigators have shown that the gastric juice does not destroy tubercle bacilli except after prolonged action for twenty-four hours or more. The experiments have not demonstrated, however, that the gastric juice is a favorable medium for the growth of the bacilli and in this fact may lie the explanation of the rarity of tuberculous gastritis and frequency of tuberculous enteritis. Only occasionally is chronic ulcerative tuberculosis of the lungs complicated with gastric tuberculosis and the question naturally arises, what are the special predisposing factors that lead to its development in these exceptional cases? Przewoski<sup>1</sup> after describing five examples of tuberculous gastritis notes that in all the cases it concerned a fibrous form of pulmonary tuberculosis and points out that this prolonged chance for infection may be of decisive importance. In two of the cases there were present the lesions of an old gastric catarrh which may have enacted the rôle of predisposing cause. It will be recalled, however, that catarrhal lesions of the stomach are frequent in chronic pulmonary tuberculosis. And then Przewoski suggests that the number of lymph follicles in the wall of the stomach may be of importance. It is in the lymph follicles that the tuberculous infection of the small intestine begins. The number of lymph follicles in the human stomach is a varying one; at times the follicles may be numerous, especially about the pylorus and in the cardiac region, and tuberculous ulcers develop most frequently in the pyloric portion of the stomach. In case the tuberculous material remained for some time in the stomach there would be greater chance for infection about the pylorus than elsewhere. Hence there are a number of local conditions in the stomach which, coupled with more or less permanent and well-marked alterations in the gastric juice, may give opportunity for the localization of tubercle bacilli, especially when these are supplied constantly for a long time and in considerable numbers. As far as we know now tuberculosis of the stomach can not be said to have any great clinical significance. Still, it is noteworthy that it has been mistaken for carcinoma. Symp-

toms of gastric cancer in the tuberculous and phthisical should consequently awaken suspicion of tuberculous gastric lesions. At the same time, the gastric symptoms, particularly if mild, may be the result of other pathologic conditions that predispose to tuberculous infection. Tuberculous gastric lesions the result of the introduction of tubercle bacilli with the food do not seem to occur because no cases of this nature have been recorded.

#### A NATIONAL, NOT A LOCAL EXAMINING BOARD.

We print in this issue a communication relative to the recent proposition for a voluntary national examining board, which seems to us to indicate some misapprehension on the part of the writer. It is not and has not been the idea that this national board should have its exclusive residence in the national capital. It was specially stated that it included examinations at different centers and it is hardly likely that the Middle West or even the more remote regions would be ignored. As to the matter of recognizing already-issued state licenses, we do not see how this can be done. Indeed, it is contrary to the essential idea of the examining board which must be something different from the state boards and entirely independent of them, as regards its work and standards. Indeed, it is expected that its standard will be up to if not above that of any of them, as they have been and are at present, and to have it recognize and endorse qualifications which it has not tested would defeat its object. The idea of the national examining board is to have one qualification, open to all, that shall be equal to that demanded anywhere in this or other countries, that shall be recognized by the general government as an essential for all medical appointments under it, and that can be endorsed by state examining and registration boards as fully meeting all their requirements, except in the matter of fees. It may be that some states may not endorse it at once, but if it is accepted by some it will in time come to be accepted by all and the problem of reciprocity will be solved. To meet all these requirements it is necessary that the standard should be high enough to make it unreasonable for any state board to attempt setting a higher one. Such being the case, there could be no reason for such board to fail to recognize it. The details of the organization and working of a national board are not difficult and suggestions are numerous that will occur to any one. It is well that the subject is brought prominently before the profession so that its discussion may be full and ample prefatory to active measures for its realization. It may not be denied that it will seem somewhat like a hardship to many old practitioners that they can not take, or rather pass, the examination and receive the license. This, however, will be found, we think, less serious in practice than in theory, and in any event no greater hardship is imposed than now exists. No state medical laws need be repealed and state boards of registration can still have the same liberty of action as they now possess. A state examination will still be sought by the majority. But over and above these will be a universal qualification available to anyone who can meet the requirements and which will in time, we believe, come to be the one sought by the ambitious young

1. Virchow's Archiv, 1902, clxvii, 424-442.

graduate. As stated before, the benefit from such a board would be for the future, rather than the immediate present. The creation of this board should not affect the efforts that are being made for reciprocity. There will be just as much need of this to relieve existing conditions.

## Medical News.

### CALIFORNIA.

**Hospital Purchased.**—Dr. James M. Shannon has purchased from Mrs. Belden of San Francisco the East Bay Sanatorium property at Oakland.

**San Juan Health Board.**—San Juan has organized a board of health, with Dr. Frank H. Patterson as secretary and Dr. John Crawford, inspector.

**Hospital for Deaf and Dumb Institute.**—The new hospital building at the Deaf, Dumb and Blind Institute, Berkeley, is nearly completed. The building has cost \$6500. Dr. Oliver D. Hamlin, Oakland, will have charge of the hospital.

**Convictions for Illegal Practice.**—After two trials in which juries failed to agree, Mrs. Annie D. Howe has been convicted at Oakland of practicing medicine without a license.—Chang Ke Hong paid a fine of \$100 in Santa Clara, May 2, for illegal practice of medicine.—F. M. Hoque, San Jose, a vendor and manufacturer of a salve which he claimed would cure cancer, was found guilty of practicing medicine without a license, but recommended to mercy.

**A Correction.**—The medical department of the University of California has notified us of an inaccuracy in our mention of the combined course in natural science and medicine which has been inaugurated at that institution. Under the new regulations students who have taken the three years' pre-medical course at Berkeley are admitted to regular freshman standing. The new course combines two years of work in sciences with the first two years' work in the medical department. The course consists of the freshman and sophomore years' work in the College of Natural Sciences, devoted largely to physics, chemistry, biology, German, and French. The first two years of the medical course, consisting entirely of instruction in the pure medical sciences, are then elected as the junior and senior years' work in natural sciences, and upon the completion of these four years the student is granted the degree of B.S. Following this the student enters upon the study of the clinical branches of medicine, and after two years receives the degree of M.D. The essential element in the new regulation consists in the election by the student of natural science of anatomy, physiology, pathology and bacteriology as his advanced scientific work, the last two years in the course of natural sciences being elective. The two years' work in the College of Natural Sciences now offered in this course practically corresponds to the collegiate work which, under the new requirements for admission to the medical department, will be made obligatory upon all entering students.

### COLORADO.

**Denver University Medical Department** graduated a class of 10, May 12. Rev. David Utter delivered the address to the class and Chancellor William H. Buchtel made a brief address on the past and future of the school.

**Resolutions on Deceased Member.**—At a special meeting of the Pueblo County Medical Society, held at Pueblo, May 1, resolutions were adopted recognizing the integrity of the late Dr. Pembroke R. Thombs and expressing regret, sympathy and condolence.

**Plague Quarantine Continued.**—At the semi-annual meeting of the State Board of Health, held April 14, it was decided to continue the bubonic plague quarantine order, which forbids entrance into the state from any point of any Chinaman who can not produce a certificate of health showing that he has not been exposed to bubonic plague during the six weeks immediately preceding his entrance.

**Death and Disease.**—The State Board of Health reports 769 deaths for the month of April, a death rate of 16 per 1000 per annum. Of these 20 were due to diphtheria; 17 to scarlet fever and 12 to typhoid fever. During the month 90 cases of diphtheria, 268 of scarlet fever and 29 of typhoid fever were reported. This shows a decrease as compared with March of 46 cases of diphtheria, 52 of scarlet fever and 5 of typhoid fever.

### CONNECTICUT.

**Tuberculosis Hospital Opened.**—The new hospital for tuberculous patients erected on Cedar Mountain at a cost of \$47,000, was opened for the inspection of the public, May 1. In the morning the physicians of the city, donors to the hospital fund and city officials were present and in the afternoon the general public were admitted.

**Infectious Diseases Reported.**—The report of the State Board of Health for April shows that during the month, infectious diseases as follows were reported: Measles, 127 cases in 26 towns; scarlet fever 338 cases in 54 towns; cerebrospinal fever, 1 case; diphtheria, 113 cases in 35 towns; pertussis, 68 cases in 11 towns; typhoid fever, 37 cases in 16 towns, and consumption 18 cases in 11 towns.

**April Mortality.**—There were 1191 deaths in the state during the month of April. This was 48 less than in March and 62 less than in April of 1901, and 111 less than the average number of deaths in April for the five years preceding. The death rate was 16.1 for the large towns, for the small towns 14.7, and for the whole state 15.7. The deaths reported from infectious diseases were 252, being 21.1 per cent. of the total mortality.

**Internships for Yale Men.**—The following men, after their graduation in June, will take positions on the house staffs of hospitals as follows: E. S. Brackett to the General Hospital, Providence, R. I.; H. E. Adams to the City Hospital, Hartford; J. J. Dunleavy and E. C. Krause to St. Mark's Hospital, New York City; V. A. Kowalewski to the Bridgeport Hospital; A. C. Swenson and L. F. Turner to the New Haven General Hospital.

### ILLINOIS.

**Dr. Fisher's Will Probated.**—The will of the late Dr. Fisher of Le Roy was admitted to probate, May 8. The estate is valued at about \$50,000.

**New Hospital at Macomb.**—The new Catholic Hospital to be erected at Macomb, will accommodate from 40 to 60 patients, and is expected to cost \$25,000.

**Instruments for St. Mary's Hospital.**—The Illinois Zine Company has presented St. Mary's Hospital, La Salle, with an operating-room equipment at a cost of \$2000.

**Gift to Hospital.**—Jacob Zorger of Clinton has announced that he will give \$5000 toward the building fund of a hospital in that city and \$5000 toward its endowment.

**Presentation to Dr. Smith.**—The physicians of Bloomington, on the occasion of the seventieth birthday of Dr. Lee Smith, presented him with a handsome oak rocking chair.

**Dr. S. T. Glasford, Pekin,** who we announced last week had located in St. Louis, writes to say that he is in St. Louis only for some special work and will return to Pekin later.

### Chicago.

**Personal.**—Dr. James V. Chvatal has been appointed a member of the Board of Education.—Dr. William Allen Pusey has moved his office from 103 State Street to 65 Randolph Street.—Dr. Fred Drury Hellenbeck has moved to 183 Rush Street.—Dr. John C. Bryan has been elected president of the Menoken Club.

**Landlords Must Heat Flats.**—Landlords of flat buildings have been forced to furnish heat to tenants during the recent cold spell, notwithstanding that leases read that heat is furnished only from September to May. The Department of Health has received many complaints and has issued orders which have been obeyed.

**College of Physicians and Surgeons.**—The medical department of the University of Illinois held its twentieth annual commencement in Chicago May 20. Dr. Walter S. Christopher delivered the doctorate address; Prof. T. J. Burrill, Ph.D., LL.D., acting president of the university, conferred degrees and announced honors, and Dr. Sherman M. Kyes, valedictorian, responded for the class, which numbered 222.

**Raw-Water Disease.**—Too much untreated hydrant water is still being drunk, notwithstanding the daily bulletins of the department showing the quality of the lake water. The frequent rains of the last few weeks have produced the usual pollution, and 11 deaths from typhoid fever were reported during the week. Deducting 2 of these, which were contracted elsewhere, the remaining 9 typhoid deaths are a wholly unnecessary sacrifice to ignorance or criminal negligence. All hydrant water intended for drinking purposes should be boiled.

**Influenza and Suicide.**—During the first 17 days of the month there have been 30 suicides—a tribute to the evil influence of the influenza poison upon the nervous system. Alienists

especially and the medical profession generally are at last aroused to the baneful import of this disease, which has been more or less prevalent throughout the world since the fall of 1889. The large increase in the demand for bacterial examinations in the laboratory during the past fortnight was due entirely to influenza, the bacillus of which is found with increasing frequency.

**New Hospital Rules.**—Warden Healy of the County Hospital has adopted a rule prohibiting patients from other hospitals from entering the County Hospital. When a patient operated upon at a private hospital is sent to the County Hospital and dies there, the impression is given out, according to the County Hospital officials, that the patient died because of the care he received at the County Hospital. By another recent ruling the following patients will not be taken to the clinic: Any patient who would suffer in any way discomfort or actual injury; any patient who is in danger of sudden death and any patient who would be discouraged or displeased because of going to the clinic.

**The City's Mortality.**—There were seventy-eight fewer deaths in the week ended May 17 than in the week before, and the total, 471, or an annual death-rate of 13.48 per 1000, is the lowest in twenty-one weeks. The reduction represents a decrease of 13.2 per cent. in the annual death rate. The principal reduction has been in the age period under five years, a reduction which has been continuous for the last three weeks. Coincident with this has been a steadily improving quality of the milk supply. Of the total 574 samples of milk and cream examined last week in the laboratory only 24 or 4.1 per cent. were found below grade. This establishes a new record in the milk division.

#### INDIANA.

**Dr. Eastman No Better.**—We regret to announce that Dr. Joseph Eastman is reported to be gradually getting worse, and little hopes are entertained for his recovery.

#### MARYLAND.

**Free Antitoxin.**—The authorities of Baltimore County will furnish antitoxin to the poor without cost.

**Railway Hospital at Brunswick.**—A small hospital has been established at Brunswick, Md., for the treatment of injured resident railway employees.

**Hospital Site Selected.**—A lot has been selected for the Cambridge, Dorchester County, Hospital, 240 by 420 feet, and costing \$2500. It is situated in the residence section of West Cambridge. The last legislature appropriated \$10,000 for the institution.

**Personal.**—Dr. Charles W. Wainwright of Princess Anne, Somerset County, has been appointed by the Governor a member of the Lunacy Commission.—The Baltimore County Sanitary Board organized at Towson, with Dr. J. F. H. Gorsuch as president, and Dr. T. Ross Payne as secretary.—Dr. E. E. Stonestreet, Rockville, has been elected health officer of Montgomery County.

**Vaccinators and Sub-Registers Appointed.**—The following physicians have been appointed vaccine physicians and sub-registers of Anne Arundel County for the next year: Drs. Guy Latimer, Benjamin R. Davidson, William G. Williams, George Crane, John M. Hayes, J. W. Dubois, C. P. Carrico, J. B. Robinson, C. R. Winterson, T. B. Horton, W. Clement Claude, Frank H. Thompson, Geo. T. Dent and G. Hall Perrie.

#### Baltimore.

**Professor Welch to Deliver the Huxley Lectures.**—Dr. William H. Welch has been chosen to deliver the Huxley lectures this year.

**Fire in Kelly Sanatorium.**—A fire broke out in the cellar of Dr. Howard A. Kelly's Sanatorium, May 14, but was extinguished before much damage was done.

**Eye, Ear and Throat Hospital Report.**—The annual report of the South Baltimore Eye, Ear and Throat Charity Hospital and Dispensary, which was opened May 1, 1901, shows 433 cases treated, 2061 visits to the dispensary and 82 surgical operations performed.

**Personal.**—Dr. John Montgomery West, a graduate of the Johns Hopkins Medical School, 1901, sailed, May 13, for Europe, where he will spend a year and a half in German hospitals.—Dr. Morris C. Robins has been appointed medical assistant to the State Board of Health at a salary of \$1000. This office was created by the last legislature.—Drs. Stephen H. and John H. King sailed for Europe May 21.—Dr. Wm.

H. Gaddess, who has been the resident physician at the Hebrew Hospital for the last two years, has resigned and will engage in private practice.

**New Clinical Building for Johns Hopkins Medical School.**—The present amphitheater will be torn down and a new building erected in its site to cost more than \$100,000. It will be 100 by 112 feet, a five-story-and-basement brick building, harmonizing with the other hospital buildings. On the basement floor there will be accident rooms, dispensary, waiting and operating rooms. The first floor will have Dr. Osler's dispensary and rooms for accident patients, also a large lecture hall, examining and class rooms, etc. On the second floor there will be rooms for patients from the hospital and vaults for records. The third floor will be devoted entirely to teaching by Dr. William S. Halstead, and will contain pathologic, bacteriologic and clinical laboratories, museum, examining room and a large lecture hall which will seat 200 students. The fourth floor will be devoted solely to surgery. There will be an anesthetizing room, preparatory room, operating room, sterilizing room, operating amphitheater, chief surgeon's office, recovery room, waiting rooms, etc. The top floor will be used for photography, and will be well lighted by a large skylight. The building throughout will be finished and equipped in a thoroughly modern way.

#### MASSACHUSETTS.

**Hospital Bequests.**—By the will of the late William Skinner of Holyoke, \$10,000 is devised to the Holyoke City Hospital and \$5000 to the House of Providence Hospital in the same city.—The will of Benjamin Henry provides that on the death of Mrs. John C. Howard, Los Angeles, Cal., the sum of \$4000 shall be paid to the Franklin County Hospital, Greenfield.

**Millions for Hospital.**—The Peter Bent Brigham Hospital Corporation was formed May 8, under the will of Peter Bent Brigham, who died twenty-five years ago, leaving his estate in trust for hospital purposes. This trust expires on May 25, making \$4,000,000 or more available for a new hospital in Boston. Brigham for a generation kept a concert hall in Court Street.

**Personal.**—Dr. George P. Hunt, Carney Hospital, Boston, has opened an office in Pittsfield.—Dr. Charles C. Holcombe, Lee, has resigned as medical examiner for the Fourth Berkshire district.—Dr. Charles F. Branch, Amherst, has been appointed medical examiner, vice Dr. Herbert B. Perry, removed.—Dr. John S. Hitchcock, Northampton, has been elected a member of the local health board.—Dr. Thomas Howell, assistant superintendent of Worcester Insane Asylum, has been elected superintendent of the Worcester City Hospital, vice Dr. Charles A. Peabody.

**Laboratory Positions Open.**—Prof. W. T. Porter has announced that three of the places recently offered by the Harvard Medical School to properly qualified men desirous of training in physiologic research and in the management of large laboratory classes in experimental physiology are not yet filled for the next collegiate year. Excellent opportunities are afforded to the holders of these places, and, besides the valuable amount of scientific knowledge that may be acquired by association with the large staff engaged in research, \$400 is paid annually to each assistant. Applications should be sent to Professor Porter at the medical school, No. 688 Boylston Street, Boston.

#### MICHIGAN.

**Detroit College of Medicine** graduated a class of 48, May 8. Dr. Theodore A. McGraw conferred the degrees; Dr. Don M. Campbell delivered the faculty address, and Dr. William T. Power was valedictorian. Rev. Nehemiah Boynton delivered the address of the evening on "Professionalism in Life." A banquet followed, at which Dr. J. Henry Carstens officiated as toastmaster.

**Mortality in Michigan.**—According to returns to the Department of State, there were 2850 deaths in Michigan during the month of April, a decrease of 109 from the preceding month. The death-rate, however, 14.1 per 1000 estimated population, was the same as that for March. There were 492 deaths of infants under 1 year of age, 219 deaths of children aged 1 to 4 years, inclusive, and 865 deaths of persons aged 65 years and over. Important causes of deaths were as follows: Pulmonary tuberculosis, 206; other forms of tuberculosis, 37; typhoid fever, 37; diphtheria and croup, 31; scarlet fever, 30; measles, 35; whooping cough, 25; pneumonia, 354; influenza, 45; cancer, 134; accidents and violence, 153.

**Butterworth Hospital Staff.**—The board of trustees of Butterworth Hospital, Grand Rapids, has chosen the following

staff: Dr. George K. Johnson, chief of staff; visiting physicians, Drs. John B. Hilliker, Henry Hulst, John A. McGill, Clarence H. White, Ralph H. Spencer, Joseph Albright, William F. Hake, Elizabeth Earle, and Herbert M. King; consulting physicians, Drs. George K. Johnson and Eugene Boise; visiting surgeons, Drs. Perry Schurtz, Hugo Lupinski, J. Orton Edie, Collins H. Johnston, Charles E. Hooker, Richard R. Smith and William G. Young; consulting surgeons, Drs. George K. Johnson, and Samuel R. Wooster; eye, ear, nose and throat, Drs. Reynold J. Kirkland, John Rogers, D. Emmet Welsh and Louis A. Roller; skin diseases, Dr. Charles E. Hooker; pathologist, Dr. Joseph B. Whinery, and Dr. Apted, house physician.

**Personal.**—Dr. Guy L. Noyes, Ann Arbor, demonstrator of ophthalmic and aural surgery in the University of Michigan, has been made professor of ophthalmology in the University of Missouri.—Drs. John H. Kellogg, William H. Haughey and George W. Green have been appointed as consultants to the health officer of Battle Creek.—Dr. Thomas M. Coen has been elected health officer of Grand Rapids.—Dr. Jesse O. Parker has been appointed health officer of Owosso.—Dr. William A. Burnham, Hancock, has been appointed physician at the Trimountain mine.—Dr. Robert W. Erwin has been re-elected president of the Bay City Board of Health.—Dr. Robert J. Davison, Foresthill, has moved to Shelby.—Dr. T. Bennett Scott, Vernon, has located in Owosso.—Dr. John W. Doyle, St. Joseph, has moved to Fond du Lac, Wis.—Dr. John H. Kellogg, Battle Creek, sailed for Europe May 10.—Dr. Henry R. Morris, Sebawaing, has sold his practice to Dr. Wilhelm W. Kahn of Frankmunth, and will take advanced studies in the East.—Dr. John F. Cardwell, Durand, has located in Toledo, Ohio.

#### NEW JERSEY.

**Hospital Items.**—By the will of the late James Atkinson, \$1000 is left to the Paterson General Hospital.—More than \$20,000 has been expended in building and furnishing the isolation hospital at Camden.—The new hospital at Perth Amboy is now open for patients. It cost nearly \$30,000.

**New Jersey Sanatorium for Tuberculosis.**—The first meeting of the commissioners recently entrusted with the establishment of this institution was held in Newark April 30. The following officers were elected: President, Dr. Charles J. Kipp, Newark; vice-president, President Austin Scott, of Rutgers College; treasurer, Col. Edward A. Stevens, of Castle Point, Hoboken, and secretary, Dr. James S. Green, Elizabeth. It is the duty of the commission to select a site and erect suitable buildings for a sanatorium for indigent citizens of New Jersey afflicted with tuberculous diseases.

**Mercer's Medical Staff.**—The following medical staff has been appointed for Mercer Hospital, Trenton: Medical director, Dr. William Elmer; consulting physicians, Drs. William Elmer and Cornelius Shepherd; consulting surgeons, Drs. Thomas H. MacKenzie and Samuel W. Latta; gynecologist, Dr. Joseph B. Shaw; assistant gynecologist, Dr. Edward S. Hawke; pathologist, Dr. Ira M. Shepherd; assistant pathologist, Dr. Harry M. Andersen; attending surgeons, Drs. John Bruere, John S. Jamieson, Nelson B. Oliphant, and William McD. Struble; and resident physician, Dr. Daniel M. Hoyt.

**Personal.**—Drs. William Edgar Darnall and Emery Marvel have been placed in charge of the newly-established department of gynecology in the Atlantic City Hospital.—Dr. John W. Bennett has been re-elected president of the Long Branch Board of Health.—Dr. Frank D. Gray, Jersey City, has sailed for Europe, where he will spend a year in study.—Dr. Walter B. Johnson has been elected surgeon, and Dr. J. William Atkinson, assistant surgeon of the Paterson Eye and Ear Infirmary.—Dr. Rolland D. Tomlinson, Plainfield, has located in Atlantic City.—Dr. Samuel A. Heffer has been re-elected president of the Hoboken Board of Health.

#### NEW YORK.

**Bequest to College.**—The Albany Medical College has been bequeathed six valuable lots near Kansas City by the will of Dr. D'Estrang Dickerson of Kansas City, a graduate of the class of 1857.

**Medical Staff Resigns.**—The entire medical staff of the hospital at Jamaica, L. I., has resigned because of the refusal of the women board of managers to rescind a resolution providing for a double staff, including homeopathic as well as regular physicians.

**Faculty Changes.**—At a recent meeting of the faculty of the Albany Medical College, Dr. George Blumer was recommended for appointment as professor of pathology and bac-

teriology; Dr. Willis G. Macdonald, professor of abdominal and clinical surgery; Dr. Samuel R. Morrow, who resigned as professor of anatomy, was recommended for appointment as professor of the practice of surgery and orthopedic surgery; and Dr. Joseph D. Craig as professor of anatomy. The following appointments were made: Theodore J. Bradley, Ph.G., lecturer on inorganic chemistry; Dr. Spencer L. Dawes, lecturer on materia medica, and Dr. Arthur Sautter, instructor of genito-surgery and dermatology.

#### New York City.

**Students Tribute to Dr. A. Jacobi.**—As Prof. A. Jacobi has resigned as professor of diseases of children at the College of Physicians and Surgeons, Columbia University, the present graduating class intend to present to him a farewell salutation engrossed in Latin on parchment.

**Knife Blade in a Man's Heart.**—A young man who applied for admission at Bellevue Hospital May 6, and who was then thought to be suffering from alcoholism and pneumonia, died May 14, and the autopsy showed hemorrhage into the lungs and a portion of a knife-blade imbedded in the sternum and pericardium. The man had a lot of toughs for boon companions, and was known to have been badly beaten May 3.

**Commencements.**—Long Island College Hospital held its commencement May 16. Out of a class of 35, 26 were graduated.—The thirty-ninth annual commencement of the New York Medical College and Hospital for Women was held May 14. Rev. D. Asa Blackburn addressed the students; Dr. M. Belle Brown administered the Hippocratic oath and Mrs. Mary Knox Robinson conferred degrees on a graduating class of six.

**Lying-In Hospital Needs Funds.**—The fact that J. Pierpont Morgan spent more than \$1,500,000 on the property and the magnificence of the new hospital has led most persons to believe that provision had been made for maintaining this institution. An appeal to the public explains that this is not so, and that the society must depend upon public generosity for about \$60,000 of the \$90,000 that it will cost to support the hospital each year.

**New Surgical Dressing.**—Dr. Robert T. Morris exhibited before the last meeting of the Surgical Section of the Academy of Medicine a new absorbent material for surgical dressings. It was found in bulk in the market under the name of "sulphite laps," and was used in the manufacture of paper. It is made by the action of sulphuric acid on wood, but is neutral in reaction. It is said to be not only very cheap, but far more absorbent than either absorbent cotton or gauze.

**Wholesale Milk Inspections.**—There have been so far about three times as much money imposed this year in fines upon milk dealers than for the same time last year, and a large number of suits are now in progress, the chief charges being dilution of milk with water, skimming off of cream and the improper use of preservatives in milk. That the present administration means business was emphasized the other night when fifty inspectors of the board of health and an equal number of sanitary policemen went to all the depots and landings for milk in the city and took hundreds of samples of suspicious milk for analysis. The milk in the cans must not have a higher temperature than 50 F.

#### Buffalo.

**Personal.**—Dr. Charles Bingham has been appointed interne at the German Deaconess' Hospital.—Dr. Charles Howard has been chosen president of the board of managers of the Elmira Reformatory.

**Dr. James M. Anders.** Philadelphia, addressed the Medical Section of the Buffalo Academy of Medicine on the subject of "Jaundice," with reports of cases. Previous to the meeting Dr. Anders was the guest of honor of a luncheon by Dr. Allen Jones and of a dinner at the Saturn Club by Dr. Charles G. Stockton.

**The Separation of the County Hospital from the Almshouse** is again under discussion. The Overseer of the Poor under the present conditions does not favor sending city patients to the county hospital because it stigmatizes them as paupers, so that during the past year the city has expended \$50,000 in sending its indigent to private city hospitals.

**Unification.**—As an illustration of the present trend toward unification of the medical profession, two prominent physicians in homeopathy, one the secretary of the New York State Homeopathic Society, have voluntarily applied for membership in the Erie County Medical Association and have been accepted. These physicians are to be regarded as regular practitioners. It is expected that many others will follow their example and soon the profession of New York State will indeed be united.

# PENNSYLVANIA.

**Coatesville Hospital.**—Subscriptions to the amount of \$25,000 have now been received for the erection of a new hospital at Coatesville, and the building will be commenced at once.

**Allentown Hospital.**—The new wing to Allentown Hospital, erected at a cost of \$33,000 by the munificence of James K. Musser, and furnished by other citizens, has been opened. The new building will accommodate 75 patients.

**New Hospital for Johnstown.**—A project for a new public hospital in Johnstown is well under way. Dr. John W. Hamer is president of the provisional board of directors, whose membership includes Drs. William J. George and Ira E. Sloan. A site for the hospital has been purchased for about \$6000.

**Bound to Fee Bill.**—Fifteen physicians of Carbondale have agreed to adhere strictly to a fee bill, and accept no society, lodge or poor board work, except at regular fee-bill prices. They have further promised that for the filling out of all affidavits, death claims, insurance examinations or other papers in which there is a money consideration, they will always make a charge, never less than fifty cents.

## Philadelphia.

**Jefferson Commencement.**—At the commencement of Jefferson Medical College, May 29, the Hon. Charles Emory Smith will deliver an address.

**Dr. Nicholas Murray Butler,** president of Columbia University, New York, will deliver the oration at the commencement exercises of the University of Pennsylvania, to be held at the Academy of Music, June 18.

**Chair Declared Vacant.**—The trustees of the Medico-Chirurgical College have declared the chair of genito-urinary surgery, occupied by Dr. Elwood R. Kirby, vacant. No reason for this radical action has been officially made public.

**Women Graduate.**—The fiftieth annual commencement of the Woman's Medical College of Pennsylvania was held May 21. On the evening of the same day, a reception from 8 to 11, in honor of the graduating class, was given at the college building by the corporators and faculty.

**Insane Department Overcrowded.**—The superintendent of the Philadelphia Hospital recently reported to a special legislative committee that there were 1444 patients in the insane department of the hospital. The proper capacity of the department is 900 to 1000. With 60 per cent. of the inmates insanity existed in the family; 10 per cent. of the cases were ascribed to alcoholism, leaving 30 per cent. due to other causes. The enactment of more rigid marriage laws was recommended.

**Municipal Hospital To Be Moved.**—The first decided move toward the removal of the municipal hospital and pest-house from its present location has been made. The council's committee on city property recommend the purchase of 62 acres of land for \$115,000, situated at Kensington Avenue and Oxford turnpike. This is near the Montgomery County line, on the outmost limits of the city, and yet readily accessible from the center by trolley lines. The ground is elevated, is thought to be well adapted to the purpose, and will in all probability be secured.

## GENERAL.

**Tua-tua for Leprosy.**—The South American plant called tua-tua is said to have properties highly effective in the treatment of leprosy. Dr. Shorey, food inspector of the Honolulu Board of Health, is conducting an investigation of the properties of the plant.

**Few Lepers at Guam.**—Commander Schroeder, naval governor of Guam, reports the finding of some of the lepers whom the Spanish had segregated at the Asan hospital, who escaped during the interregnum following the Spanish withdrawal. These have been concealed by the natives. Some eight have been found, and it is doubted whether many other cases exist. Governor Schroeder says there is no evidence that the disease has been disseminated by the lepers during their freedom. The population of the island of Guam, although variously estimated, is probably about 12,000, and the native portion is decreasing slowly. Aside from the army and navy forces of perhaps 600, foreigners number about 300, including many Japanese. The lepers will be segregated on the shores of a beautiful bay a mile east of the capital.

**The Anti-malarial Campaign in Italy in 1901.**—The Italian Adriatic R. R. entrusted Dr. Ricchi last year with the task of protecting their personnel over their entire lines in upper and middle Italy which pass through some of the most malarial regions known. The measures already described were

carried out at every station: wire netting over doors, windows and chimneys, spring doors to netting vestibules and also to the bedrooms inside the house, hats protected by a veil of wire netting with a curtain of soft gauze attached to the lower edge to be tucked into the clothing, and gauntlet gloves. The expense was not so great as anticipated, and the results showed that only 2 per cent. of the perfectly protected employees contracted malaria, and only 13.31 per cent. of the less perfectly protected, while 38.71 per cent. of the control population were affected. About 212 houses with 1600 persons, station agents and their families were completely protected, and 25 houses with 406 inmates were the entirely unprotected control material. The total number of persons under observation was 2657, of whom 2009 had previously suffered more or less from malaria. The latter were treated with quinin during the pre-malarial season, but after it opened all medication was suspended. Dr. Schiavuzzi of Trieste has been commissioned to do a similar work for the Istrian R. R. on the east shore of the Adriatic.

**Examination for Marine-Hospital Surgeons.**—A board of officers will convene at the Marine-Hospital Bureau, 3 B street, S. E., Washington, D. C., June 16, for examining candidates for the grade of assistant surgeon in the U. S. Marine-Hospital Service. Candidates must be between 21 and 31 years of age, graduates of reputable medical colleges, and must furnish testimonials from responsible persons as to character. The following is the usual order of the examinations: 1, physical; 2, oral; 3, written; 4, clinical. In addition to the physical examination, candidates are required to certify that they believe themselves free from any ailment which would disqualify for service in any climate. The examinations are chiefly in writing and begin with a short autobiography of the candidate. The remainder of the written exercise consists in examination on the various branches of medicine, surgery and hygiene. The oral examination includes subjects of preliminary education, history, literature and natural sciences. The clinical examination is conducted at a hospital and when practicable, candidates are required to perform surgical operations on a cadaver. Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order as vacancies occur. Upon appointment, the young officers are, as a rule, first assigned to duty at one of the large marine hospitals, as at Boston, New York, New Orleans, Chicago or San Francisco. After five years' service, assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Promotion to the grade of surgeon is made according to seniority and after due examination as vacancies occur in that grade. Assistant surgeons receive sixteen hundred dollars, passed assistant surgeons two thousand dollars, and surgeons twenty-five hundred dollars a year. When quarters are not provided, commutation at the rate of thirty, forty and fifty dollars a month, according to grade, is allowed. All grades above that of assistant surgeon receive longevity pay, ten per cent. in addition to the regular salary for every five years' service up to forty per cent. after twenty years' service. The tenure of office is permanent. Officers traveling under orders are allowed actual expenses. For further information, or for invitation to appear before the board of examiners, address Supervising Surgeon-General, U. S. Marine-Hospital Service, Washington, D. C.

**The Philippine Cholera Order.**—In view of the threatening aspect assumed by cholera in Manila the following general order, No. 58, was issued March 23, 1902, from the Headquarters of the Philippines:

1. Asiatic cholera is a disease the infection of which is taken in by the mouth: as a preventive measure it is therefore necessary to eat or drink only articles in which the infective principle has been destroyed by distilling, cooking, etc. Unboiled water, including aerated waters not imported, and sorbete, the native ice cream, fresh vegetables of any sort, as lettuce, cabbage, fresh fruits, etc., which are not cooked in their preparation, are, therefore dangerous and to be avoided. In addition, the greatest care must be given to the preparation of foods and dishes on which they are prepared or served. The infection may be carried by washing such dishes with infected water or by wiping them with cloths which have been washed in such water.

2. All officers stationed in this division will give personal instructions and care to see that no member of their family or servant in their household drinks water that has not been distilled, or if not distilled, that has not been thoroughly boiled for at least twenty minutes, or any aerated waters except those imported, or sorbete, or eat fresh vegetables or fruits of any sort which has not been thoroughly cooked. Further personal care and superintendence is enjoined in the use of boiled water in the washing of dishes and thorough boiling of the cloths which may be used to wipe such dishes. The irresponsibility and ignorance of native cooks render careful personal supervision of the kitchen imperative in order to avoid this disease.

3. The same care is enjoined as specified in the preceding paragraph in the use of water and preparation of foods in barracks or other buildings or camps where enlisted men or government civilian employees are stationed. All soldiers and all U. S. civilian employees

in this division are forbidden to use water for drinking obtained from rivers or wells in the vicinity of Manila unless the same has been distilled or thoroughly boiled. No excuse for ignorance in regard to this will be accepted, and proper disciplinary measures will be applied for any detected violation of this paragraph.

4. In order to prevent possible infection of food by flies, company commanders and other persons in the military service or attached thereto, in charge of messes, are enjoined to take the necessary measures to protect all food from flies and other insects. That this may be carried out food should not be placed on the table until immediately before it is to be served and should be covered at all times. The attention of company commanders and other persons in the military service or attached thereto, is called to the necessity of care in covering the contents of dry earth or other closets with earth or chlorid of lime, in order that flies may not have access to such contents with possible later transference of infectious material by such flies to foodstuffs.

5. As the Division Commander can not be certain that saloon-keepers will not serve unsterilized water for customers to drink, all persons in the military service or civilian employes therewith, are directed to confine their drinks at saloons, if they drink at all, to beer.

6. A sentinel or responsible watchman will be posted at every faucet where water is obtained from city water mains for Army use, and such sentinel or responsible watchman will be instructed to permit no person to drink thereat.

7. All officers and employes of the transport service, ships chartered or otherwise employed in the military service will be at once warned to comply strictly with the foregoing regarding consumption of vegetables, etc., and drinking water.

8. All persons affected with diarrhea or vomiting will report themselves immediately to their medical officers for treatment.

9. All cases of cholera or cases suspicious of that disease coming to the notice of medical officers will be immediately reported by telegraph to the chief surgeon of the division.

10. Cholera having made its appearance in Manila, careful attention to diet and the use of water rendered safe by boiling, with the avoidance of insanitary localities, are all necessary in order to secure immunity from that disease.

11. This order will be read to all troops as soon as received and a copy kept posted in all barracks, quarters and camps.

**San Francisco Plague Report.**—The following record of the autopsy findings on the last case of plague in San Francisco will be of interest. The patient was Chin Sney Kim, aged 30, male, who arrived from Davisville, Cal., on the evening of April 17, took quarters at Man Fook On's undertaking establishment at 838 Clay Street, and died at 5 a. m., April 20, 1902.

Autopsy at 2:15 p. m. Body well nourished. General postmortem lividity unusually well marked in places, especially over the biceps of the arms; the body was almost black. No signs of wounds, lesions or trauma. No glandular enlargement noted by palpation, but a sense of increased resistance over the right femoral region.

Incision made over right femoral region, and several enlarged, necrotic, hemorrhagic edematous glands discovered. Smears from these showed bipolar coccobacilli decolorizing by Gram's, having every appearance of bacillus pestis.

Abdominal cavity opened. Intestines and appendix normal. No fluid in abdominal cavity. Spleen enlarged to five times normal. No signs of portal obstruction to account for such enlargement; rather soft; capsule tense; no subcapsular nodules. Surface almost uniformly pink with a few slightly pigmented areas; pulp bulging very slightly; connective tissue increased.

Lungs adherent to pleural cavity by rather fresh, soft adhesions, especially the right. No fluid in pleural cavity. Surface of heart normal. Left ventricle hypertrophied and empty. Right contained fluid. Right and left auricles contained postmortem blood clots and fluid blood. Left lung normal size, pleura glistening, except the adhesions before mentioned. A few subpleural hemorrhages, organ crepitated throughout, pitted on pressure. Cut surface moderately rich in blood. Air, blood and serum exuded on pressure, in the usual proportions. Right lung covered with blood-stained lymph exudate, a pleurisy of several days' standing; cut rather firmly, cut surface moderately rich in blood; crepitated throughout. Air, blood and serum exuded on pressure.

Left kidney: fatty capsule normal in amount. Organ as seen through fibrous capsule had a white appearance in which the vena stellata were prominent. Organ enlarged and softer than normal. Fibrous capsule removed easily, exposing a very lightish yellow surface; cut surface moderately rich in blood; contrast between cortex and pyramids fairly well retained in areas and lost in others. Blood vessels injected throughout organ. Kidney normal in appearance (white kidney, early stage). Liver enlarged to about one-quarter above its normal size; capsule very tense; of a general reddish appearance; with mottled areas of light reddish-yellow; capsule smooth, glistening and transparent; no hemorrhages on subcapsule. Softer than normal; cut very easily, cut surface rich in blood; structural appearance well retained.

Endocardium, surface of aorta, and coronary opening, apparently normal. Heart muscles of left ventricle thickened, normal appearance, showing neither fibroid nor fatty change; 2 or 3 sub-endocardial hemorrhages.

Stomach empty. Intestines: mesenteric glands enlarged; no injection of intestines; small intestines opened; blood vessels found injected and follicles enlarged. One of enlarged mesenteric glands removed and found to be neither injected nor necrotic. Bladder completely empty.

Incision made in left femoral region, although there was no appearance or indication of glandular enlargement, nor could glands be felt by palpation, yet the glands were found to be moderately enlarged, necrotic, and slightly edematous; being imbedded in quantities of fat, they could not be felt. Incision made in right axillary region and glands found in same condition. One such gland was found in left axillary region. Smears from spleen showed a few bacilli, which appeared to have been partially disintegrated, although some of them still retained their bipolar staining qualities.

Anatomic diagnosis: Pleurisy, fibrous exudate; acute pulpitis of spleen, and chronic connective tissue increase of same; venous con-

gestion of liver; hypertrophy of left heart, bubonic plague; septicemic plague. Cause of death, bubonic plague. (April 25, confirmed bacteriologically.)

**Opinion of Ohio, Indiana and Kentucky on Plague in San Francisco.**—At the annual conference of the boards of health of these states, the smallpox situation was thoroughly discussed. The following action was taken on the plague scandal in California:

We, the representatives of the State Boards of Health of Ohio, Kentucky and Indiana, together with representatives of the county and city boards of health of Indiana, in conference assembled in the city of Indianapolis, April 25, 1902, in view of certain documentary evidence before us, do resolve as follows:

1. We view with surprise and alarm the acts of the Governor of California and the Mayor of San Francisco, in attempting to suppress the facts relating to the presence of bubonic plague in that city. We are surprised at such attempts because we regard the facts as fully established and beyond all question. The Board of Health of the City of San Francisco, composed of honorable gentlemen distinguished for their scientific attainments, and holding the entire confidence of their associates and the public, published the facts in their monthly report to the city government, submitting therein all necessary data. The existence of the plague in said city was afterwards confirmed, by an expert, sent there by the United States Marine-Hospital Service, also by an expert employed by the State Board of Health, and finally by a commission of eminent bacteriologists of international fame, whose sole interest in the matter was to know the truth.

2. We view with alarm this attempt to suppress the fact of the presence of an epidemic disease, the most deadly known to medical science, because with bubonic plague and cholera in a number of ports on direct communication with that of San Francisco and with the energies of the governor of the state and the mayor of the city directed to the suppression of truth rather than the plague, what guarantee has the interior that it will long be exempt from the pestilence.

3. We condemn and deplore the acts of the governor of said state in attempting to discredit the competency and veracity of the experts above mentioned; for forcing the resignation of certain members of the State Board of Health because they concurred in the expert conclusions; for seeking to unduly influence the United States Treasury Department, and for making denial of the existence of plague a condition of appointment to the vacancies caused by the above resignations.

4. We condemn and deplore the act of the mayor of San Francisco in co-operating with the governor as above set forth, and for removing from office the city board of health of San Francisco for no other reason than that in the faithful discharge of the duties imposed upon them by law, and their endeavor to protect the lives and health of the citizens of that metropolis, they published the presence of the plague, and maintained their honor against all contrary influences.

5. We further declare, it is beyond our comprehension how any member of the honorable profession of medicine, conscious of the dignity of this high calling, and zealous for maintenance of that dignity could accept appointment to vacancies thus created under the condition expressed or implied.

6. We affirm that in every state, territory and municipality of the United States where the representatives of the people have enacted laws for the protection of the lives and health of their citizens and have appointed boards whose duty it is to execute those laws, the citizens of said states, territories and municipalities have a right to hold said boards to the faithful performance of their duties, and to the prompt and effectual use of every means which the law allows and sanitary science approves for the prevention of the introduction and the spread of epidemic diseases.

7. We further affirm that in the employment of such means, it is absolutely necessary to notify the public of the presence of said epidemic disease, point out the locality in which it has appeared, indicate its progress, etc., in order that the public, having knowledge, may co-operate in its extinction.

8. We further affirm that in pursuance of these measures and in answer to the rightful demand of citizens for protection, infected houses should be placarded conspicuously, and if found necessary, guards should be employed and detention and isolation hospitals erected; in the employment of which measures together with general disinfection publicity should be courted rather than avoided.

9. We further affirm that, where the responsibility of protecting the public health rests solely upon said boards, no other authority, however high, should thrust itself between them and their duties, and where individuals or corporations interfere to prevent the discharge of said duties, such should be made amenable to the law.

Lastly, we call upon sanitary associations, boards of health, medical and scientific associations throughout the country to join with us.

The above expression was fully discussed and finally adopted unanimously by the conference. The following gentlemen from other states were in attendance: Pres. Byron D. Stanton, and Sec. Charles O. Probst of the Ohio State Board of Health; Pres. Wm. Bailey and Sec. J. N. McCormack of the Kentucky State Board of Health. All of these gentlemen formally concurred in the above action in regard to plague in San Francisco.

### Smallpox.

Colorado: Compared with March the month of April shows an increase of 37 cases; the number reported for the month was 291. The number of cases is, however, 139 less than in April, 1901. The State Board of Health has established a definite period for quarantine of smallpox, providing that the minimum period of quarantine for those suffering from smallpox shall be not less than four weeks from the beginning of the eruption, and in any case not less than ten days after scaling is completed.

Connecticut: Smallpox has almost entirely ceased. Fresh cases of the disease have appeared since the last bulletin was issued, in only a few towns. This peculiar exemption of Connecticut, as compared with other states, can only be attributed to the protective influences of vaccination. School visitors have required vaccination as a prerequisite to attendance of pupils. Health officers have advised and promoted vaccination in many towns in advance of an invasion of the disease and so the people have been protected.

Even in the towns not so prudent, the vigilance of health officers in isolating the primary cases has limited the disease in most instances to few cases. The conspicuous exception was in Waterbury, where the disease appeared in a block of tenements occupied mostly by French-Canadians. Even there it would have been controlled if prompt notification of its presence had been given. Its spread in Waterbury is alleged to have been due to the pernicious influence of an anti-vaccination society existing there, whose members have been charged with encouraging the concealment of the disease, and with bold assertions publicly made that the disease among them was not smallpox. By request of the mayor and the health authorities of Waterbury two members of the State Board of Health visited and personally inspected the patients in the hospital and in private houses and in every instance found only typical cases of smallpox. The diagnosis was still further confirmed by the evidence of Dr. C. N. Valin, an eminent specialist from Montreal whom the French people themselves employed in order that their doubts should be fully removed.

The number of cases reported in Waterbury was 79, which far exceeded that of all the other cases in the state during the year. How much its extensive prevalence there, with all its expensive and distressing results, is chargeable to the baneful influence of the anti-vaccinationists can be best appreciated by those who know all the facts. The practice of vaccination and the isolation of the existing cases promptly arrested its spread.

This office is in receipt of reports of 141 cases occurring within a year. Only one case has been reported in the last three weeks. A very large majority of these were never vaccinated. Seven of them had been vaccinated from 7 to 40 years before. There were eleven cases about which reliable information has not been given respecting vaccination. All the others were unvaccinated. All of the deaths were of the not-vaccinated. How can the anti-vaccinationists explain these facts?

Illinois: The Department of Health reports that ten out of the nineteen new cases discovered last week were among colored people, and since the first of the year this factor of the population, numbering only 1.3 per cent. of the total, has furnished 35 per cent. of all cases. The colored pastors, physicians, lawyers and other influential leaders of the race, having been made acquainted with these facts, are taking steps to secure general vaccination and to promote sanitation among their people in order that this stigma may be removed.

The situation is less hopeful in other respects. An immigration movement of enormous proportions is flooding the northwest with thousands of the newly-arrived who are passed on from ports of arrival into the interior without any supervision as to their vaccinal condition. Chicago, as the great distributing point, is peculiarly exposed and appeals have been made by the commissioner to the federal, state and local authorities to enforce proper precautions at ports of entry to the end that no immigrant or his belongings may leave such ports until vaccination and disinfection have made it certain that they shall not be carriers of contagion into the country.

Kansas: Of the 457 cases of smallpox reported in Kansas during April, only one resulted in death.

Maryland: Dr. John S. Fulton, secretary of the State Board of Health, reports 25 cases of smallpox in the state: 9 in Allegany County, 2 in Washington County, 1 in Baltimore County, 1 in Queen Anne's County, 4 in Caroline County, 2 in Talbot County, 1 in Dorchester County, and 5 in Baltimore City. Others officers report a case of smallpox in Caroline County, and 1 in Dorchester County.

Michigan: During April smallpox was reported at 236 places in the state, 9 places more than in the preceding month. Five deaths were due to the disease.

New York: Lately several cases of smallpox have been concealed in this city and vicinity by faith-healers or those in sympathy with them. A particularly flagrant example of this crime against the community occurred in Newark, and was only discovered through the publication in the official paper of the sect of an article boasting of the recovery from smallpox of a man through the "laying on of hands and through the influence of the Holy Ghost." The woman who did the nursing and her son both contracted smallpox, the former becoming blind as a result.

Puerto Rico: It is reported that, thanks to the effective measures taken by the local sanitary board, under the direction of the sanitary officer, Dr. Lopez Gastambide, the varioloid epidemic is rapidly decreasing.

#### CANADA.

**The Montreal Dispensary.**—The fifty-second annual meeting of the Montreal Dispensary was held in that city last week. The secretary's report for the committee of management showed that during the past official year the applicants for advice and treatment had numbered 16,675. The medical and surgical cases numbered 8505; eye and ear, 2069; women's diseases, 1725; nose and throat, 912; skin diseases, 1725; children, 1327; dentistry, 154.

**Insane in the Toronto Jail.**—The special civic committee of the Toronto municipal council, which has been enquiring into certain charges preferred by one of the aldermen with regard to the confining of insane people in the Toronto jail, has had its report adopted by the council. At the time of their visit to the institution they found thirty-one lunatics lodged within the walls. In addition to these there were a number of idiots, imbeciles from birth. The report recommends that the Provincial Secretary take steps for the prompt removal of the insane to proper asylum quarters.

**Personal.**—Dr. Russell Thomas, Lennoxville, Quebec, secretary of the St. Francis District Medical Association, has gone as medical officer with the fourth contingent to South Africa. —Dr. R. E. McKechnie, Nanaimo, B. C., is spending three months in a post-graduate course at McGill University. When that is finished, he will go to New York and thence to England and the continent. —Dr. A. F. Mayburry, Toronto, has gone to England and Vienna for a post-graduate course in nose and throat. —Dr. William Corlett, Cleveland, will give a lantern demonstration on the exanthemata at the coming meeting of the Canadian Medical Association in Montreal in September.

**Dominion Registration Passes Its Final Stage.**—When Dr. Roddick's Bill for the establishment of the Dominion Medical Council came before the senate, or upper house of the Canadian Parliament, three important amendments were made. No province shall be represented on the council either by elected or appointed members until after the said act had been adopted by the legislature of the province, and had thereby accepted the registration under this board with the provincial board in lieu of the registration with the provincial board. A clause was also added that the act shall not interfere as conveying any power to open medical schools or give medical education. Provision was further added which would prevent the act from becoming retro-active. Subsequently the Commons concurred in these amendments; and the Governor-General has affixed his signature to the bill, which appears among the legislation of the past session as "An Act to Provide for the Establishment of a Medical Council in Canada." Dr. Roddick can well be congratulated upon the success which has attained his efforts, especially so when it is remembered that this subject has been agitated with more or less vigor since the Confederation of 1867.

#### FOREIGN.

**Mexico Hospital Improvements.**—The hospital of the St. Vincent de Paul Society, in the City of Mexico, for the treatment of the poor, is to be enlarged and have its facilities increased.

**Virchow's Resignation.**—Virchow has gone to the watering place Teplitz-Schönau for the summer, and has resigned the presidency of the Berlin Medical Society, which he has held for twenty years.

**Prefers Money for Hospital.**—King Edward has expressed the desire that the offerings customarily made the ruler in honor of the coronation should be in the form of additions to the king's hospital fund.

**Medical Women at Medical Congresses.**—The recent German Congress of Internal Medicine had two women as members for the first time. Our exchanges also mention that the chairman of the section of surgery at the recent Russian Medical "Pirogoff" Congress was a woman, Dr. A. G. Archangelskaia.

**Sanitary Homes in Germany.**—The architects in the service of the government are now required to attend a two weeks' course of lectures on sanitary dwelling houses. The lectures are delivered by the official chief of the architect service, and by a physician, Professor Kossel. The attendance at a single course is restricted to 20, and the lectures are given in the Institutes of Technology at Berlin and Hanover. The *Deutsche Med. Wochenschrift* considers this arrangement a very important progress in the line of sanitation.

**Important Congresses in Europe During September.**—The International Conference for the Prevention of Syphilis and Venereal Diseases opens at Brussels, September 1 to 6. This is followed by the International Congress of Gynecology at Rome, September 15 to 21, and the Seventy-Fourth German Congress of Naturalists and Physicians "of theory and practice" at Carlsbad, September 21 to 28. The Second International Congress of Electrotherapy and Radiography meets at Berne, September 1 to 6. The first was held at Paris in 1900. The French Congresses of Surgery and of Urology also usually meet at Paris in September.

**France Is Disquieted Over Health Affairs** in her colonies. Leprosy exists in most of them, cholera has cost thousands of lives, other infectious diseases are on the increase and foreign residence and enterprise are made very dangerous. Dr. J. Crespin, a professor in the school of medicine at Algiers, was commissioned by the French Minister of the Interior to study sanitary conditions in the Persian Gulf. He reports the danger of the infection of Europe through the Persian Gulf to be great, and recommends the island of Ormuz as a quarantine and examination station for all vessels. Persia is also worried over the danger. Some French papers urge a conference of European powers to co-operate in sanitary measures.

**Sanatorium for Venereal Diseases.**—The Berlin insurance company "Landesversicherungsanstalt Berlin" has derived such pecuniary benefit from its sanatoria for its tuberculous policy holders, that it has now erected a similar sanatorium for venereal diseases. It expects to save much expense by the thorough treatment of its policy holders in a closed institution, where they will not only be cured, but contagion of others will be prevented. During the absence of the breadwinner in the sanatorium a pension will be paid to the family. The company has issued an appeal to all the sick insurance societies and to physicians in general urging them to coöperate and to do all in their power to remove the prejudice which may prevent persons affected with venereal diseases from entering such an establishment. It is arranged for fifty beds and takes only men, but if it proves successful, it will be enlarged and others built.

**Plague in Australia.**—Our regular London correspondent gives this week statistics of the situation in Australia and from a Sydney correspondent we learn additional facts. The plague is an indirect benefit in one particular—the cities are being cleaned of refuse, old unused sewers closed up, and other places of refuge for rats are being removed. In Sydney, disinfectants and rat-poison have been distributed free for the past three months, and when the scare was at its worst 3000 applicants were supplied daily. Phenyl and chlorid of lime are the disinfectants used, arsenic and phosphorus the rat poisons. The total cost of these to the middle of April was \$3000, aside from the wages of the inspectors, cleaners, rat-killers, etc. Sydney is a wide-awake and up-to-date city fortunately, for she is constantly exposed to danger of disease from the immense amount of shipping that comes to her harbor from every part of the world.

#### LONDON LETTER.

##### Smallpox Decreases.

The epidemic of smallpox, which has prevailed so long, at last shows a tendency to decline. The number of cases in the metropolitan hospitals is 1442, against 1431 and 1515 in the preceding weeks; 250 new cases were admitted during the week, against 274, 328 and 367 in the three preceding weeks. The deaths last week were 43, against 73, 42 and 42 in the three preceding weeks. Since August 6879 cases have occurred, of which 1175 have been fatal; in addition 874 extra-metropolitan cases have been admitted to the metropolitan hospitals, of which 132 were fatal.

##### Typhoid Fever in South Africa.

In the House of Commons Mr. Broderick, Secretary for War, gave some interesting figures as to the epidemic of typhoid fever, which has proved such a serious obstacle to the British army in South Africa. In the three months, December, 1901, to February, 1902, 6379 cases occurred among the troops, causing 953 deaths; in the corresponding period of last year there were 5905 cases and 1042 deaths. During the last few months most of the cases have come from the moving columns, and comparatively few occurred in the camps and stationary garrisons where special precautions are enforced as to boiling of the water.

##### Statistics of the Plague.

In the week ending April 12 there were in India 1100 deaths more than in the previous one, the total mortality amounting

to 24,380. In Bombay City a rapid decline has taken place: for the week ending April 5 there were 947 deaths, ending April 12, 696. In the Bombay Presidency the corresponding figures were 3170 and 2093; in Calcutta 603 and 689. In Bengal the deaths during the week ending April 12 were 603, in the Northwest Provinces and Oudh 1660 (against 1570 in the previous week), in the Punjab 16,281 (against 14,871), in Cashmere 212, against 416; in Mysore 80, against 173. In Egypt, during the week ending April 27, 18 fresh cases and 8 deaths occurred; during the month of April there were 102 fresh cases and 58 deaths. Since April 7, 1901, when the disease reappeared in Egypt, the total number of cases was 484, of which 281 were fatal. During the week ending April 5, 2 fresh cases occurred in Cape Colony: two natives were found dead, which shows that the disease is concealed. During the week ending April 12 there were 5 fresh cases and 3 deaths. The total number of cases of plague up to date is 885, with 427 deaths. At Hong Kong, during the week ending April 26, there were 5 cases and 5 deaths; ending May 3, 28 cases and 26 deaths. In Australia, during the present recurrence, 109 cases have occurred, of which 27 were fatal. Twenty-one animals, including two birds, have died of plague in Sydney, in the Zoological Gardens. At Brisbane a few cases occur daily.

##### Army Medical Reform.

Previously in THE JOURNAL we have referred to the scheme of reform of the Army Medical Department which the government has brought forward under pressure of the so-called "hospital scandals" in the South African war. The complete new regulations are now published. On the whole they are a distinct advance and should greatly improve the service. The entrance examination is greatly changed and made completely clinical and practical. It will be partly written and partly oral. Thus, in medicine the written part will consist of examining and reporting on a case in a hospital, 125 marks being allotted for the examination and 125 for the commentary thereon. The oral examination in medicine will consist of clinical cases (75 marks), and morbid anatomy and histology (75 marks). In surgery there will be a similar examination and report on a case. In the oral examination clinical cases, including diseases of the eye, surgical instruments and appliances will be the subjects (75 marks) and operative surgery and surgical anatomy (75 marks). Candidates who gain places will undergo two months' instruction in hygiene and bacteriology, after which they will be examined in these subjects. Then they will proceed to the depot of the medical corps at Aldershot for three months' instruction in technical duties of the corps, which will be again followed by an examination. A lieutenant on probation who fails to qualify in either of these examinations will be allowed a second trial, and should he fail will be placed at the bottom of the list. Should he again fail his commission will not be confirmed. For promotion to captain an examination in regimental duties, drill, military law, military hospitals and other executive duties must be passed. For promotion to major an examination must be passed, which may be taken at any time after completing five years' service. The subjects will be medicine, surgery, hygiene, bacteriology and tropical diseases, and one special subject from the following list: bacteriology (including preparation of antitoxins), dental surgery, dermatology, laryngology, midwifery and gynecology, operative surgery (advanced), ophthalmology, otology, pediatrics, psychological medicine, skiagraphy and specific fevers. For promotion to lieutenant-colonel there will be an examination which may be taken any time after three years in the rank of major. The subjects will be military law, army medical organization, sanitation of towns, camps, transports, epidemiology and a special subject from this list: medical history of important campaigns, army medical service of other powers, and laws and customs of war in relation to the sick and wounded.

##### The Dangers of Celluloid.

From time to time during the last 10 years cases of severe burns from the accidental catching fire of celluloid ornaments and collars have been recorded, both in the lay and the medical press. In 1898 the *Lancet* appointed a commission to investigate the subject which showed, by placing a celluloid comb in a wig at varying distances from a glowing fire, the probability of accidents to wearers of such an article. It was further found that a curling iron heated to the temperature necessary for curling readily started the evolution of dense and highly inflammable fumes. Later, the *Lancet* showed the danger of exposing celluloid toys in shop windows near electric lamps. The following illustrate the accidents from celluloid: A man while smoking a cigar was playing an American organ with

celluloid keys. Some red-hot ash dropped on the keys, and they burst into flames, which were extinguished with difficulty. A boy was wearing a celluloid collar tied with string. To remove the collar he burned the string. The collar ignited and lighted drops of the composition fell on his clothing. His throat and face were badly burned. In the *Lancet* of February 22 Professor Ogston of Aberdeen describes the case of a woman who, seated before a fire which was not unusually strong, found her hair enveloped in smoke and flame from ignition of the comb. Before the flames could be extinguished an area of the scalp of 4 by 1½ inches was destroyed. The burn was of the third degree, and the hair of the injured area was permanently destroyed. It is urged that government should interfere and compel the manufacturers of celluloid to render it less inflammable.

#### International Congress on the Protection of Children.

This Congress will be held in London, July 15 to 18, under the presidency of the Earl Beauchamp, K.C.M.G. It will consist of four sections: 1, medical; 2, legal; 3, educational, and 4, philanthropic. The following are among the interesting subjects on the program: How far parental authority and responsibility should be recognized after the state has had to take charge of a child. What pressure can be put on parents who neglect their children so as to discourage others from a similar offense. Regulation of street trading by children. The relation of the state toward migratory, destitute, neglected and criminal children. The American system of probation officers. The reclamation of vicious children. Papers to be read should be forwarded to the assistant secretary, Mr. W. G. Lewis, 8 Wells Street, Gray's Inn Road, London, W. C.

### Correspondence.

#### The Proposed National Board of Medical Examiners.

PHILADELPHIA, May 17, 1902.

To the Editor:—The soundness of the legal principle, that the regulation of the practice of medicine for the protection of the public comes within the general police powers of the state, is now regarded as fully established. Nearly four centuries ago the first statute was adopted in England for regulating medical practice. The preamble to this Act (3 Henry VIII, cap. ii) recites that physic and surgery were then practiced by "ignorant persons, who could tell no letters on a book, and by common artificers, smiths, weavers and women, who took upon themselves great cures: partly using sorcery and witchcraft, partly applying very noxious medicines to the disease." This statute enacted, under penalty, that no one should practice medicine without going before a board of examiners and receiving its approval. Since 1511, the date when this law was passed, many others have been enacted, all assuming that the authority to regulate the practice of medicine belongs to the state, as a measure of protection of the community against incompetence and fraud. The recognition of this principle, and the acceptance of the implied obligation, in this country, has led to the establishment of the various state medical boards, and boards of examiners and licensers, which now exist in nearly every state of the union. The good work already done by these boards, in the direction of raising the standard of medical education among college graduates, and in keeping out of the ranks of the profession imperfectly trained and incompetent applicants, is now generally conceded and gratefully appreciated by those who are interested in the welfare and have regard for the solidarity of the medical profession.

In the practical working of the law under which these state boards act, however, there has been developed a very serious drawback, owing to the fact that they are restricted in their jurisdiction to the geographical limits of the commonwealth from which their authority issues. The examining boards have their duties strictly defined. They are allowed no discretionary powers which would permit them to step beyond the letter of the law, which, as interpreted by them, requires only one form of examination to be employed, whether the applicant is a recent graduate, or he already possesses the right to practice in another state under the license of that state board. No concession can be made to the veteran, who already has good standing and who may have in his former place of residence

acquired distinction, or even conferred honor upon American medicine. This is an opprobrium to the entire profession of this country, as long as it is allowed to continue. Men of the highest attainments who occupied professorial positions, being invited to membership in the faculty of a college in another state, have been compelled to sit down with neophytes and to be examined, possibly by some of their own pupils. The situation is embarrassing both to the distinguished guest and to the members of the board, who are simply doing their duty under the law.

In point of fact the legislation was never intended to apply to the higher ranks of the profession at all, but merely to guard the door of entrance against unqualified intruders. The president of the Pennsylvania State Board of Medical Examiners, Dr. Henry Beates, has given much time to the consideration of this unfortunate condition of affairs, and has labored to bring about a sort of interstate comity, by means of which the certificates of one state may be accepted as valid in another. He frankly confesses, however, that, as matters are at present, owing to the varying standards in force in different states, this plan is impracticable. Dr. Beates has recently suggested that the state boards shall establish a practitioners' examination, which shall be entirely clinical and practical. In other words, that there shall be two examinations: one for recent graduates, the other for practitioners, and of the latter at least five years' practice of medicine would be required. He believes that a certificate obtained by this special examination, would be regarded as valid in every part of the country by mutual agreement among the state boards.

An effort will be made at the Saratoga meeting of the American Medical Association to arrive at a solution of the difficulty by another route. Dr. William L. Rodman has made a very practical suggestion.<sup>1</sup> In brief, his plan involves the establishment of a voluntary board of national examiners, supplementary to the existing state organizations, to consist of six members, viz.: the surgeons-general of the Army, Navy and Marine-Hospital (Public Health) Service, and three representative civil practitioners, two to be elected by the House of Delegates of the American Medical Association, and one by the American Congress of Physicians and Surgeons. The proposed (voluntary) examinations are to be both theoretical and practical, and are to be held in Washington, or some other convenient large city, where hospital facilities can be utilized. It is hoped by the author of this plan that the certificate or diploma of such a distinguished board would be accepted, as a matter of courtesy, by state authorities anywhere in the Union, as satisfactory evidence of the owner's professional attainments and personal worth.

It is said that this plan has been unanimously endorsed by the delegates from the several state boards, meeting with the Committee on National Legislation recently in Washington, and that it will be recommended to the House of Delegates at the coming meeting. It may also be stated here that the president of the Pennsylvania Board of Examiners favors it and hopes that it will be adopted.

A number of years ago, the writer, while editor of the *Philadelphia Medical Times*, being impressed with the hardship imposed by this anomalous situation, suggested tentatively a plan that has some of the features of Professor Rodman's plan. It similarly contemplated a voluntary examination before a national board, and was based upon the acknowledged efficiency of the tests employed by the medical examining boards of the U. S. Army and Navy. It proposed that such examinations might be opened to civilians who did not intend to enter the public service, but who simply desired the distinction that would accrue from passing such a government or national board. The successful candidates could have an endorsement of the fact upon their diplomas. When thus fortified, it was believed that a *modus vivendi* could be established, through the courtesy of the state boards, by which diplomas with such endorsement could be accepted as sufficient evidence of the owner's proficiency anywhere in the United States, without further examination, except for personal identification. It is very evident that

any solution that is offered, if it is to be carried into practice, will ultimately rest upon the favor of the several state boards and their willingness to co-operate. Very probably additional legislation may be required in order to give them the power of discriminating, so as to recognize the distinction between the two classes of candidates: 1, those who are required to demonstrate their fitness for the responsibilities of medical practice and, 2, those about whose fitness there is no question whatever. As a means of affording present relief to the members of the latter class, the writer would make the suggestion that the state medical societies might consent to co-operate with the examining boards. For instance, if a reputable member of the profession, who has been actively engaged in practice, for, say, ten years, desires to change his field of work he can apply for a certificate from his state medical society, which could be endorsed by the medical society of the state to which he is going. Such evidence of professional attainments might well be accepted by the examining board of the state concerned, and thus aid in carrying out the idea of interstate comity or reciprocity, while recognizing and upholding the dignity of the profession.

Very respectfully yours,

FRANK WOODBURY.

### A Voluntary Board Will Not Accomplish the Result Desired.

NEW YORK, May 17, 1902.

*To the Editor:*—I have read with great interest the article of Dr. Rodman in the issue of THE JOURNAL of the 10th inst. and your very able editorial on the same. You having invited a free expression of opinion pro and con, I take the liberty to analyze it and point out wherein I differ. The evil that this voluntary board of national examiners is expected to remedy is supposed to be this: that a graduate of a medical college of high standard, holding a certificate from a state board, is compelled to pass an examination in case of his removal to another state.

Will this proposed board accomplish the result? Any state which demands an examination from one possessing credentials of registration in a state with a high medical standard, will also refuse to recognize a license of a national voluntary board: as a matter of fact the multitude of examinations we are blessed with in this country are for the purpose of barring a brother practitioner from locating in that state.

Were it not for that, what excuse is there to demand an examination from a physician who has registered and was allowed to practice? It is un-American as well as unjust. Where is the fair play we Americans are proud of?

Your editorial admits that, should the volunteer national board be realized and all the states consent to relinquish their rights to the national board, this would only assist those that would pass the examination of the board, and no relief is suggested to the thousands of physicians who are in practice. What should the practitioner do who is unfortunate, and on account of sickness is compelled to change climate? The young man can take care of himself, he can pass an examination wherever he goes, but the older man, though he may be rusty on technical points, is far advanced on practical points, and to him the doors are closed. It is ridiculous that a man who was good enough for the community of one state should not be allowed to practice in another state.

What is the remedy for the multiple examinations of every state? The Association should put itself on record that every state which comes up to the standard should reciprocate, in other words, every licensed physician, whether he has passed a state examination or was exempt from it by reason of previous registration, should be allowed to register on the presentation of proper credentials, on paying the fee according to law.

We ought to be honest about it. When a physician is good enough, in a state that comes up to the standard, why should he be rejected by another state? The objection that the man who registered before the law passed does not come up to the standard is not well taken, because he has the advantage of experience instead. Some of the best teachers have never passed a state examination and some were even students of a

two-year course. Their constant work and perseverance in study after graduation, combined with experience, raised them far above the average. Dr. Rodman further states: "The Committee on National Legislation, representing the A. M. A., has reported, advising against reciprocity and in favor of a national board of examiners. The committee had, however, been working upon the hypothesis that such a board could be created and sustained by act of Congress. Letters read from . . . caused the committee to drop the idea of a national board created by act of Congress as such legislation would certainly be unconstitutional and in conflict with the several states. The states are sovereign and can not be coerced by the general government." A national board would be for the benefit of the community against impostors, and every state which is mindful of the common welfare would come under its folds sooner or later by its own free will. There would be no objection to a national board when accepted by a voluntary relinquishment of rights on the part of the state. But such a board must first have the stamp of the country at large, by an act of Congress, which would give it the high standing and reputation to gain the respect of the whole nation, as well as of foreign countries. The high standing of the surgeons-general of the Army, Navy and Marine-Hospital Service is not so much on account of their superior knowledge as it is on account of their position representing the national government. If such a board were made national it would then compare with the Royal College of Physicians.

I would suggest that a national body be created by Congress, to be called "The Commission of Health of the United States," with headquarters in Washington, to have supervision over all medical matters of the United States, such as the granting of certificates to candidates after successful examinations, which should suffice for the medical departments of the Army, Navy and Marine-Hospital Service, and for any state or territory which by consent relinquished its state authority. This commission should supervise the manufacture of drugs, chemicals, serum, etc. This commission should not interfere in commerce, acting only when requested by the manufacturer to examine his goods, and if they be found to be up to a standard, to issue a certificate to that effect. The members of the commission should consist of the surgeons-general of the Army, Navy and Marine-Hospital, and one member for every state, to be elected by the American Medical Association, yearly, of such states that consent to relinquish their state authority to the commission. And this commission should have a salaried officer to be in charge all the time with salaried assistants to carry on the duties of his office. Very truly yours,

L. W. ZWISLOCK.

1085 Lexington Avenue, New York City.

### A Broader National Examining Board.

JEFFERSON CITY, Mo., May 15, 1902.

*To the Journal:*—The medical profession has not been altogether wise in its efforts for state regulation of the medical art. In the very eager pursuit of the charlatan the dignified and careworn family physician was almost forgotten. Under the medical laws of the several states he has less freedom of movement than the plumber or the iron molder. Physicians do not always change location for a moneyed consideration, but oftentimes to engage in special work, or to lighten their labor, as the means of a longer and more comfortable life. We alone are responsible for the unfortunate condition, and we must apply the remedy. If the American Medical Association decides to create a voluntary national examining board, let it be on broader lines than suggested by Dr. Rodman of Philadelphia. Let us at least anticipate applicants for examination from Chicago, St. Louis, Louisville and San Francisco. And let it further be hoped that there will be recognition of state licenses already issued to physicians who have passed satisfactory examinations before state examining boards. We have physicians of great merit in all the states, and if the American Medical Association takes action in this matter at all, it must be upon the basis of intellectual equality of the profession in all the states. I do not think the state boards will consent to a

disregard of past examinations made by them, but I believe they would arrange with the national board for an endorsement of such, and also agree with the national board as to a standard of proficiency for future examinations. We do not want two standards of qualification in this country, nor do we want state board jealousy and possibly avarice aroused. The national examiners should have per-diem, not fees, for services. Judicious medical legislation can come only through broad, big-minded practical men, and there are many in the American Medical Association. Are they interested?

CHARLES PINCKNEY HOUGH, M.D.

## Book Notices.

**POLK'S MEDICAL REGISTER AND DIRECTORY OF THE UNITED STATES AND CANADA.** With Index to the Physicians of the United States Arranged Alphabetically, with the Number of the Page on Which the Name Appears. Seventh Revised Edition, 1902. Cloth. 1p. 3008. Price, \$10.00. Detroit, Baltimore, Chicago: R. L. Polk & Co.

This edition of the old standby directory of the medical profession of the United States and Canada is in many respects superior to former issues and gives evidence of painstaking care by the publishers. We congratulate them upon the degree of accuracy attained in registering so many thousands of practitioners, covering so vast a territory. The medical laws of every state and territory are revised to the latest date, the medical information for the Army, Navy and Marine-Hospital Service is replete, accurate and up to date, every medical school now in operation or extinct is recorded with full particulars of each, and the name, address and graduation particulars are given. This is supplemented by the usual alphabetical index of physicians, making it possible to ascertain the present location of any physician in America. It is to be hoped that the next edition will have a more substantial binding and that the coloring of the edges will be of such a material that it will not rub off in handling. A thumb index by states would be a valuable acquisition to the volume.

**A MANUAL OF PRACTICAL ANATOMY.** By the Late Alfred W. Hughes, M.B., M.C. Edin., F.R.C.S. Edin., etc., Professor of Anatomy, King's College, London. Edited and Completed by Arthur Keith, M.D. Aberd., F.R.C.S. Eng., Lecturer on Anatomy, London Hospital Medical College, etc. In Three Parts. Part I. The Upper and Lower Extremities. Illustrated by 38 Colored Plates and 116 Figures in the Text. Cloth. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co. 1901.

This is the first of a series of three volumes intended as a guide to the dissection of the human body. The present volume describes the anatomy of the upper and lower limbs, and, so far as can be seen from our examination, the subject is presented in a most satisfactory way. The death of the author has put the work of arranging and editing the matter of the work into the hands of Dr. Arthur Keith, who has performed his task in an admirable manner, adapting the description of dissections, etc., to the later surgical procedures. The changes, however, as he says, will be more numerous in the parts yet to appear, as the present one was nearly complete at the time of the author's death. The dissection methods are adapted to the newer methods of preserving subjects. This is also an advantage. The illustrations are abundant and well selected to illustrate the text. Although most of them are taken from well-known authorities, many are original. The book is one that can be cordially recommended to the student in anatomy and will be a very valuable reference work for the surgeon.

**ON DISORDERS OF ASSIMILATION, DIGESTION, ETC.** By Sir Lauder Brunton, M.D., D.Sc., LL.D. (Edin. and Aberd.), F.R.S., F.R.C.P. Cloth. 1p. 495. Price, \$4.00. London and New York: Macmillan & Co., Ltd. 1901.

This collection of various papers published at dates ranging from 1874 to 1900 forms a very readable volume of nearly 500 pages, which may well be added to any physician's library. Of course the matter in these essays is not new, but they are all of them timely and none are out of date, notwithstanding the time that has elapsed since their first appearance. The leading idea of a number of them, as the author says in his preface, is the action of enzymes, and this is a subject that is well to the fore in physiology at the present time. The longest paper, that on stimulants and narcotics, is a quasi popular but scientific statement of the leading facts in regard to these substances

and others are almost equally practical in their tenor, though the inclusion of more strictly scientific and technical papers like those on gas absorption by the intestine and on the action of ferments keep the book within the stricter pale of purely medical works. It is of special value in giving many practical points in a clear and attractive way, and should find many readers.

**MANUAL OF CHILDREN'S NURSING, WITH NOTES ON INFANT FEEDING.** By Charles Jewett, A.M., M.D., Sc.D., Professor of Obstetrics and Diseases of Women in Long Island College Hospital. Fifth Edition. Revised and Enlarged. Cloth. 1p. 84. Price, \$0.80. New York: E. B. Treat & Co. 1902.

This little work has reached its fifth edition, which shows that it has met with popular favor. The author states that the entire contents have been revised and much new material added. So far as we can see it seems to be well compiled and to contain the principal points which the nurse should know.

## Married.

JOSEPH SHEAFE, M.D., Riverside, Iowa, to Miss Roxey Louder, of Illinois, May 6.

EDWARD T. LAMB, M.D., Alma, Mich., to Miss Mabel Ball of Petersburg, Mich., May 1.

LEAL K. SLOTE, M.D., Constantine, Mich., to Miss Mae Wilson of Jackson, Mich., May 7.

ALBERT WINN, M.D., Harris, Iowa, to Miss Dora E. Hankins of Sioux City, Iowa, May 7.

WILLIAM L. HEARST, M.D., Cedar Falls, Iowa, to Miss Jennie E. Curtis, of Chicago, May 10.

ALBERT C. JOHNSON, M.D., Sidell, Ill., to Miss Josephine Evans, of Horace, Ill., April 30.

GEORGE A. CARIART, M.D., Pittsburg, Pa., to Miss Sara Weston Kimball of Milwaukee, Wis., May 6.

GUSTAVUS W. MOLL, M.D., Forest City, Mich., to Miss May Isabel Rideout of Oshkosh, Wis., May 7.

THOMAS A. KING, M.D., to Miss Celeste Norris, both of St. Joseph, Mo., at Kansas City, Mo., May 7.

## Deaths and Obituaries.

**Ida E. Richardson, M.D.**, one of the most prominent women physician of Philadelphia, died at the age of 57, May 9. She was a graduate of 1879 from the Woman's Medical College of Philadelphia, in which she was later instructor in practice of medicine. Dr. Richardson had a large practice limited wholly to diseases of women and children. She was one of the founders of the West Philadelphia Hospital for Women, an attending physician to the Woman's Hospital, a member of the County Medical Society, and of the American Medical Association.

**John L. White, M.D.** Harvard University, 1854, one of the most prominent and widely-known physicians of Illinois, died at his home in Bloomington, May 13, after a long illness, aged 69. Dr. White settled in Bloomington in 1870, and at once assumed a leading position in the profession of the state. He served for two terms as member of the legislature and was a member of the American Medical Association.

**John H. Van Eman, M.D.** Medical College of Ohio, Cincinnati, 1868, professor of diseases of women in Kansas City Medical College, and president of its board of directors, a veteran of the Civil war, a prominent physician and gynecologist of Kansas City and a member of the American Medical Association, died at his home in Kansas City from septicemia after an illness of less than a week, aged 62.

**Marie E. Zakrzewska, M.D.** Western Reserve University, Cleveland, 1856, the pioneer woman physician of Boston, one of the pioneers of the movement that enabled women to practice in various sections of the country, and the founder of the New England Hospital for Women and Children, died at her home in Boston, May 13, aged 73.

**Pierson J. Pratt, M.D.**, a recent graduate of the University of Pennsylvania School of Medicine, died at Glen Echo, Montgomery, Md., May 4, from an overdose of morphia administered accidentally by himself. He was aged 27, and came from his home in Pennsylvania only two days before.

**Allen Fowler, M.D.** University of Maryland, Baltimore, 1867, one of the most prominent and beloved physicians of

Utah, where he had practiced for more than thirty years, died at Holy Cross Hospital, Salt Lake City, May 7, from pneumonia, after a short illness.

**John B. Wiley, M.D.**, died suddenly at his home in Gerards-town, W. Va., May 4, aged 74. He was a native of Virginia, and had resided in Berkley County twenty-five years. He was a graduate of the Medical College of Virginia, Richmond, in the class of 1854.

**Thomas F. Riegel, M.D.**, one of the resident physicians of St. Joseph's Hospital, Philadelphia, died, May 6, in that institution, from typhoid fever, aged 22. Deceased was graduated with honors in the class of 1901, from Jefferson Medical College.

**Adolph Schlernitzauer, M.D.** Washington University, St. Louis, 1864, a member of the American Medical Association, and a successful practitioner of Millstadt, Ill., died at his home in that place after a prolonged illness, May 8, aged 64.

**Sidney J. Lanier, M.D.** Medical College of Georgia, Augusta, 1884, formerly a practitioner of Savannah, but who was obliged to move to North Georgia a year ago on account of consumption, died at his old home in Oliver, Ga., May 9.

**Alfred Desjardins, M.D.** University of Michigan, Ann Arbor, 1877, who had practiced for twenty-five years in the Upper Peninsula of Michigan, died at St. Luke's Hospital, Marquette, after a long illness, May 7, aged 46.

**John W. Godfrey, M.D.** Central College of Physicians and Surgeons, Indianapolis, 1881, a widely-known physician of central Illinois and ex-mayor of Moweaqua, died at his home in that place, May 10.

**Joseph L. Pope, M.D.** New York University, 1855, died suddenly at his home in Bardstown, Ky., May 9, aged 72. He served on the Confederate side as a surgeon during the Civil war.

**John T. Milling, M.D.** Royal College of Surgeons, Ireland, 1843, the oldest practitioner of La Salle County, and coroner from 1888 to 1892, died at his residence in Peru, May 7, aged 83.

**Daniel W. Burdick, M.D.** Geneva (N. Y.) Medical College, 1862, died at his summer home near Syracuse, N. Y., after a prolonged illness from heart disease, May 3, aged 64.

**George W. French, M.D.** Northwestern University, Chicago, 1870, formerly of Owensboro, Ky., died at his old home in Grayville, Ill., May 4, from heart disease, aged 69.

**Sidney O. Morgan, M.D.** Western Reserve University, Cleveland, 1878, a resident of North Dakota for nearly twenty years, died recently at his home in Glen Ullin.

**Campbell Slayden, M.D.** University of Nashville, Tenn., 1852, died at his home in Dickson, Tenn., May 6. He was a member of the American Medical Association.

**Z. P. Landrum, M.D.** Medical College of Georgia, Augusta, 1851, a pioneer of Lowndes County, Miss., died suddenly at his home in Dunbar, May 5, from heart disease.

**James A. Corley, M.D.**, resident of Texas since 1850, died, May 6, at the home of his son, Dr. Laurence Corley, in Midway, Texas, after an illness of one week, aged 79.

**John H. Furman, M.D.** Medical College of the State of South Carolina, Charleston, 1845, died suddenly at his country home, Ramsey, S. C., May 6, aged 78.

**Christopher Adamson, M.D.** University of Michigan, Ann Arbor, 1899, died from erysipelas at his home in Bemidje, Minn., May 8, after a brief illness.

**William C. Harvey, M.D.** Transylvania University, Lexington, Ky., 1848, died at his home in Roanoke, Mo., May 7, after a short illness, aged 76.

**Ray Rickey, M.D.**, died from lung disease, after a long illness, May 6, at Belmont, Cal., where he was assistant physician to Dr. Alden M. Gardner.

**Robert A. Jenner, M.D.** Miami Medical College, Cincinnati, 1895, of East Dayton, Ohio, died at St. Elizabeth's Hospital, Dayton, May 12, aged 28.

**Andrew G. Grinnan, M.D.** University of Pennsylvania, Philadelphia, 1848, died at his home in Madison County, Va., May 9, aged 75.

**Charles N. Irwin, M.D.**, who had practiced in Mount Sterling, Ill., since 1850, died at his home in that place, April 25.

**William J. Burr, M.D.** Geneva (N. Y.) Medical College, 1845, died at his home in Newark Valley, N. Y., May 5.

**Arvid H. Winnermark, M.D.** Rush Medical College, Chicago, 1884, died at his home in Chicago, May 7, aged 45.

**George J. Hamilton, M.D.** Miami Medical College, Cincinnati, 1873, died at Eaton, Duval County, Fla., May 2.

**Samuel G. Ade, M.D.** University of Illinois, Chicago, 1897, died at his home in Chicago, May 11, aged 43.

## Societies.

### COMING MEETINGS.

**American Medical Association.** Saratoga Springs, N. Y., June 10 to 13.

**American Pediatric Society.** Boston, May 26-28, 1902.

**American Laryngological Association.** Boston, Mass., May 26-28, 1902.

**American Gynecological Society.** Atlantic City, May 27, 1902.

**Connecticut Medical Society.** New Haven, May 28-29, 1902.

**Ohio State Medical Society.** Toledo, May 28-30, 1902.

**American Laryngological, Rhinological and Otolological Society.** Washington, D. C., June 2-4, 1902.

**American Surgical Association.** Albany, N. Y., June 3-5, 1902.

**Louisiana State Medical Society.** Shreveport, June 3-5, 1902.

**Maine Medical Association.** Portland, June 4-6, 1902.

**South Dakota State Medical Society.** Scotland, June 4-5, 1902.

**Wisconsin State Medical Society.** Milwaukee, June 4-6, 1902.

**Rhode Island Medical Society.** Providence, June 5, 1902.

**Association of Military Surgeons of the United States.** Washington, D. C., June 5-7, 1902.

**American Orthopedic Association.** Philadelphia, Pa., June 5-7, 1902.

**American Academy of Medicine.** Saratoga Springs, N. Y., June 7, 1902.

**American Association of Life Insurance Examining Surgeons.** Saratoga Springs, June 9, 1902.

**National Confederation State Medical Examining and Licensing Boards.** Saratoga Springs, N. Y., June 9, 1902.

**Association of American Medical Colleges.** Saratoga Springs, N. Y., June 9, 1902.

**American Climatological Association.** Los Angeles, Cal., June 9-11, 1902.

**American Proctological Association.** Saratoga Springs, N. Y., June 10, 1902.

**Medical Society of Delaware.** Newark, June 10, 1902.

**Massachusetts Medical Society.** Boston, Mass., June 10-11, 1902.

**Medical Society of the State of North Carolina.** Wilmington, June 10-14, 1902.

**Colorado State Medical Society.** Pueblo, June 17, 1902.

**American Medico-Psychological Association.** Montreal, June 17-20, 1902.

**Minnesota State Medical Society.** Minneapolis, June 18, 1902.

**Medical Society of New Jersey.** Atlantic City, June 24-26, 1902.

**Washington State Medical Society.** Tacoma, June 24-26, 1902.

**Michigan State Medical Society.** Port Huron, June 26-27, 1902.

**American Gynecological Society.**—The twenty-seventh annual meeting of this Society is to be held at the Hotel Rudolf, Atlantic City, N. J., May 27-29, under the presidency of Dr. Seth C. Gordon, Portland, Me.

**Fulton County (Ohio) Medical Association.**—This Association met at Wauseon, April 28, and elected Dr. Edwin A. Murbach, Archbold, president; Drs. S. Parker Bishop, Delta, and Thomas Blair, Lyons, vice-presidents, and Dr. Sylvanus F. Cosgrove, Swanton, secretary.

**Clinton County (Ill.) Medical Society.**—The annual meeting of this Society was held in Carlyle, May 6. Dr. William P. Gordon, Carlyle, was re-elected president, and Dr. Theophilus Gaffner, Trenton, re-elected vice-president. Dr. Charles H. McMahon, Carlyle, was elected secretary.

**Hancock County (Ill.) Medical Society.**—At the annual meeting of this Society, held in Carthage, May 5, Dr. Charles L. Ferris, Carthage, was elected president; Dr. John J. Reaburn, Denver, vice-president; Dr. Robert L. Casburn, Carthage, secretary, and Dr. James H. Callahan, Carthage, treasurer.

**American Laryngological Association.**—The twenty-fourth annual congress of this Association will be held in Boston Medical Library Building and Harvard Medical School, May 26, 27 and 28. Dr. John W. Farlow, president of the Association, will deliver his address at the first morning session.

**Cape May County (N. J.) Medical Society.**—At the annual meeting of this Society, held in Cape May, May 6, Dr. John S. Douglass, Tuckahoe, was elected president; Dr. Joseph Marshall, Tuckahoe, vice-president; Dr. Nathan A. Cohen, Wildwood, secretary, and Dr. Randolph Marshall, Tuckahoe, treasurer.

**Carroll County (Ark.) Medical Society.**—This Society met at Eureka Springs, May 10. Officers were elected as follows: President, Dr. Adolph Krebs, Eureka Springs; vice-president, Dr. William P. George, Berryville; secretary, Dr. V. Francis Lassayne, Eureka Springs, and treasurer, Dr. Russell G. Floyd, Eureka Springs.

**Southwestern Kentucky Medical Association.**—At the meeting of this Society, in Paducah, May 8, the following officers were elected: Dr. James M. Peck, Arlington, president; Drs. Benjamin P. Earle, Charleston, and Benjamin L. Hendley, Farmington, vice-presidents; Dr. Horace T. Rivers, Paducah, secretary, and Dr. James T. Reddick, Paducah, treasurer.

**State Medical Society of Wisconsin.**—The fifty-sixth annual meeting of this Society will be held in Milwaukee, June 4 to 6, inclusive. Dr. Walter H. Neilson, Milwaukee, will preside. The courtesies of the Bon Ami Club are tendered to the members, and clinics are to be given by Drs. Harvey W. Cushing, Baltimore, and Simon Flexner, Philadelphia.

**Middlesex North District (Mass.) Medical Society.**—At the annual meeting of this Society, held at Lowell, April 30, Dr. J. Arthur Gage was elected president; Dr. Burnham R. Benner, vice-president; Dr. Wyllis G. Eaton, secretary; Dr. David N. Patterson, librarian; Dr. Joe V. Meigs, Jr., treasurer, and Dr. William B. Jackson, commissioner of trials, all of Lowell.

**Massachusetts Medical Society.**—The one hundred and twenty-first anniversary of this Society will be celebrated, June 11, when the annual meeting will be held in the building of the Massachusetts Charitable Mechanic Association, Boston, under the presidency of Dr. Frank W. Draper, Boston. Section meetings will be held in the Medical Library, 8 The Fenway, June 10.

**Southwest Missouri District Medical Association.**—At the annual meeting of this Association, held in Springfield, April 17, Dr. Richard W. Paris, Morrisville, was elected president; Dr. Norman F. Terry, Springfield, vice-president; Dr. Herbert S. Hill, Springfield, recording secretary; Dr. William P. Patterson, Springfield, corresponding secretary, and Dr. Arthur B. Freeman, Joplin, treasurer.

**Association of C., H. and D. Surgeons.**—The surgeons of the Cincinnati, Hamilton and Dayton Railway met at Dayton, May 6, and formed a permanent organization, with the following officers: President, Dr. Wilbur R. Thompson, Troy, Ohio; vice-presidents, Drs. William S. Hog, Wellston, Ohio, and Charles H. Parsons, Rushville, Ind.; secretary, Dr. Mark Milbikin, Hamilton, Ohio, and treasurer, Dr. J. Herman Thesing, Cincinnati.

**Appanoose-Wayne County (Iowa) Medical Association.**—The physicians of Appanoose and Wayne counties met at Centerville, May 8, and temporarily organized a bi-county medical society. Dr. William H. Earnest, Seymour, was made temporary president; Dr. Clyde E. Sawyers, Centerville, vice-president; Dr. Charles S. James, Centerville, secretary-treasurer, and Dr. Charles P. Bowen, Centerville, assistant secretary-treasurer.

**Hampshire District (Mass.) Medical Society.**—The annual meeting of this Society was held in Northampton, May 8, when Dr. Clarence R. Gardner, Northampton, was elected president; Dr. Albert G. Blodgett, Ware, vice-president; Dr. Arthur G. Minshall, Northampton, secretary; Dr. Alfred H. Hoadley, Northampton, treasurer; Dr. Christopher Seymour, Northampton, librarian, and Dr. Charles F. Branch, Amherst, commissioner of trials.

**Randolph County (Ill.) Medical Society.**—The physicians of Randolph County met at Chester, May 2, and organized a county society, with sixteen members, and the following officers: Dr. William R. MacKenzie, Chester, president; Dr. Alexis T. Telford, Menard, vice-president, and Dr. Henry C. Adlerly, Chester, secretary-treasurer. Dr. John T. McNally, Carbondale, president of the Illinois State Medical Society, was present and assisted in perfecting the organization.

**Illinois State Medical Society.**—The fifty-second annual meeting of this Society was held at Quincy, May 20, 21 and 22, 1902, under the presidency of Dr. John T. McNally, Carbondale. The Committee on Constitution and By-laws presented a new document, which was drafted in conformity with the plan of reorganization of the American Medical Association. It was thoroughly discussed, amended and adopted. The Committee on Medical Legislation presented the draft of a proposed bill for the regulation of the practice of medicine and establishing a board of medical examiners in the State of Illinois. This was likewise thoroughly discussed and recommended to the Society for adoption.

**American Medical Editors' Association.**—The annual meeting of this Association will convene in the Y. M. C. A. Building, Saratoga Springs, N. Y., June 9 and 10. The pre-

liminary program includes a number of valuable papers and gives assurance that the meeting will be a most successful and interesting one. An important feature will be a symposium presenting various features of editorial and business management of medical journals. The annual dinner of the Association will be given at the Hotel Kensington on the evening of June 9. The officers of the Association are Dr. Alexander J. Stone, St. Paul, Minn., president, and Dr. Otho F. Ball, St. Louis, secretary, to whom all correspondence should be directed.

**Palmetto Medical Association.**—At the meeting of this Association of colored physicians of South Carolina, at Charleston, May 1, the following resolutions were adopted: *Resolved*, That we condemn the absurd, untrue and un-Christian statements made by one Dr. W. T. English, of Pittsburg, Pa., in an article published in the *Charlotte Medical Journal*, under the caption of "Shall the Negro Be Allowed to Practice Medicine?" *Resolved*, That a committee, consisting of J. M. Thompson, of Charleston, and Dr. C. W. Birnie, of Sumter, be appointed to prepare a suitable reply to said article. The election of officers resulted as follows: President, Dr. Nathaniel J. Kennedy, Beaufort; vice-presidents, Drs. John A. Robinson, Darlington, and John M. Thompson, Charleston; secretary, Dr. C. W. Birnie, Sumter, and treasurer, Dr. William D. Crum, Charleston.

**Albany (N. Y.) Medical College Alumni Association.**—At the annual meeting of this Association, the historian made a report in which he named the following alumni who served in the Spanish-American war: Drs. James F. Smith, '98, Albany; James E. Brennan, '89, deceased, Albany; Adolph V. R. Fenwick, '99, Schenectady; Garret V. Johnson, '96, Schenectady; Bernard Livingston, '99, New York City; John Van Rensselaer, '71, Washington, D. C.; James P. Kimball, '64, Washington, D. C., and Lewis T. Griffith, '97, Troy, N. Y. The following officers were then elected: President, Dr. Walter W. Scofield, Dalton, Mass.; vice-presidents, Drs. Alva E. Abrams, Hartford, Conn.; Warren C. Spalding, New York City; William B. Sabin, Watervliet, N. Y.; Thomas H. Flynn, Somerville, N. J., and Charles R. Seymour, Binghamton, N. Y.; recording secretary, Dr. J. Montgomery Mosher, Albany; corresponding secretary, Dr. Andrew MacFarlane, Albany; treasurer, Dr. Robert Babcock, Albany, and historian, Dr. Eugene E. Hinman, Albany.

## KENTUCKY STATE MEDICAL SOCIETY.

*Forty-Seventh Annual Meeting, held at Paducah, May 7-9, 1902.*

President, T. B. Greenley, M.D., Meadow Lawn, in the Chair.

### National Legislation.

The address of welcome was delivered by Hon. D. A. Yeiser, mayor of Paducah; response by Thomas Hunt Stucky, M.D., Louisville. After the reports of various committees were read and adopted, Dr. Dudley S. Reynolds, Louisville, chairman of the Committee on National Legislation, after mentioning the work done at the third annual conference of the committee of the American Medical Association at Washington, D.C., April 10, said: "It is the opinion of your committee that the permanent establishment of an authoritative representative of the medical profession should exist in Kentucky; and that a sum sufficient to meet the necessary expenses of such representative appropriated, annually, not exceeding \$75 per year." This report was adopted.

### Smallpox.

At the afternoon session a paper on "The Value of State Control and Vaccination in the Management of Smallpox" was read by J. N. McCormack, M.D., Bowling Green. This will appear in full in THE JOURNAL.

DR. F. L. LAPSLEY, Paris, also advocated humanized virus.

DR. W. W. RICHMOND, Clinton, had seen a small epidemic of smallpox originate from a case of so-called Cuban itch.

DR. J. G. BROOKS, Paducah, had seen the contagion spread prior to development of the pustular stage, and did not agree with the essayist as to the innocuousness of such cases.

DR. D. S. REYNOLDS, Louisville, had seen the mildest cases of varicella give rise to violent variola. He recommends humanized vaccine. He has seen chancreoid sores produced by bovine virus. There is danger of introducing other microorganisms, for instance the staphylococcus. Glycerinated vaccine is objectionable, but it depends altogether upon method of introduction.

DR. J. A. LEWIS, Georgetown, said he knew some physicians who did not believe in vaccination, whose remarks had considerable influence with the laity, and had kept them from being vaccinated. He advised against vaccination upon the leg as he had seen one fatal case of this nature.

DR. ARCH DIXON, Henderson, referred to the lack of interest on part of the fiscal courts in attempting to stamp out smallpox, or in assisting physicians and health boards in doing so.

DR. GEO. ORSBORN, Sebree, had seen eight pregnant women with smallpox in recent epidemic, all of whom aborted. The disease resembled pneumonia in first stages and some difficulty had been experienced in diagnosis.

DRS. FRANK BOYD, Paducah; T. J. SHOEMAKER, Morgantown; C. C. GODSHAW, Louisville; and C. AUSTIN, Bagdad, took part in the discussion.

DR. J. N. McCORMACK, in closing the discussion, said he did not wish to be understood as condemning bovine virus, but following its use local and constitutional disturbances were apt to be more severe and immunity not so great as that following humanized virus, therefore the latter was preferable. Vaccination can most certainly be enforced under the laws of this state.

"The Obligation of Society to the Physician" was read by DR. ARCH DIXON, Henderson.

#### Fracture and Malpractice Suits.

DR. JOHN A. LEWIS, Georgetown, read "The Treatment of Fractures and Dislocations in Relation to Suits for Malpractice," and concluded with the following summary: "1. Do not undertake to practice surgery unless you have some training and skill. 2. If you undertake it, leave nothing undone to secure success, from the date of your first visit to your last, when you remove the dressing. 3. Never guarantee results: let it be clearly understood that failure is not impossible even in uncomplicated cases after the most faithful and skilful treatment. 4. Make your first examination just as carefully and thoroughly as possible under the circumstances: make a plain and truthful statement as to result of your examination of trying nature of injury, etc., to the family, guarding your prognosis well. Make this statement if possible in the presence of some honest physician or, better still, some intelligent layman. 5. Let the patient and his family feel that in calling you it is presupposed that they know your ability in work in this line; if they are unwilling to assume the risk of final results, then they ought to call someone else. 6. After your first examination, if you are in doubt as to the diagnosis, or as to plan of treatment, call a consulting physician at once. 7. In the treatment of charity patients and dead-beats be especially on guard to protect yourself. 8. Remember the law holds you to the same accountability in the treatment of charity patients as in treatment of the rich. 9. Use only approved methods of treatment, leave the experimental treatment to the hospitals. 10. Treat your brother physician exactly as you would have him treat you: never by word, or act, or look, lend countenance to the suggestion of a damage suit, it matters not whether the physician be your personal friend or not. Express no opinion as to an unsuccessful result in any case treated by another physician, unless he be present. 11. If in spite of your best efforts to avoid a suit, one comes, never compromise or pay hush money; fight to the death. Every physician should always stand ready to go to the assistance of his brother physician, with his time and money if necessary, in defending one of these suits for malpractice. 12. In closing, it may not be out of place for me to say that perhaps the wisest solution of the whole matter might be for each of you to 'lay up treasures in heaven, where moth and rust do not corrupt and thieves do not break through and steal.'"

DR. D. S. REYNOLDS, Louisville, said all the law required was that the surgeon should be competent to do what he undertook. He related several cases, however, where juries had awarded damages (in some cases punitive damages) against surgeons although it did not appear that the surgeons were at fault.

DR. F. L. LAPSLEY, Paris, asked if the surgeon were not still legally responsible, even after he further refused to treat a case, because of refusal on part of the patient to comply with the wishes of the surgeon in regard to certain treatment.

DR. J. A. LEWIS, in closing the discussion, stated that in twelve months after the patient was discharged (in Kentucky) the legal responsibility of the physician or surgeon ceased. But so long as the case is under the surgeon's observation he is held responsible. The speaker again emphasized the importance of making these examinations under anesthesia, unless there exists some valid contraindication.

The president's annual address was read in the evening at the Palmer House, and was followed by an elaborate banquet given by the committee on entertainment in honor of the Kentucky State Medical Society.

#### Puerperal Eclampsia.

The first paper on May 8 was read by DR. J. T. REDDICK, Paducah, on this subject. After a general review of symptoms and etiology, the author reported two interesting cases recently seen, both successfully delivered with forceps, followed by recovery. In one case he had removed an ovarian cystoma in the ninth week of pregnancy. Believing the condition due to a general toxemia, he advised free elimination, calomel, veratrum viride, morphin, chloral, digitalis, inhalations of chloroform, etc.

DR. W. B. GOSSETT, Louisville, called attention to enlargement of the thyroid gland in eclampsia, and suggested that the thyroid secretion might be the treatment nature had provided to overcome the poisonous toxins.

DR. E. SPEIDEL, Louisville, referred to importance of prophylactic treatment: advised elimination by calomel and injection of hot saline solution into colon. Urea and not albumin is the important factor in urine of pregnant women. A diet of buttermilk is better than sweet milk.

The next paper was read by WALKER B. GOSSETT, M.D., Louisville, on the subject of "Version."

#### The Medical Treatment of Cholelithiasis.

A paper on this subject was read by R. ALEXANDER BATE, M.D., Louisville. The author thought gallstones due to constitutional dyscrasia. Indications for treatment are, 1. prevention of formation of calculi; 2. control of symptoms and expulsion of calculi when formed. It is not claimed that all cases of cholelithiasis can be cured by medical means, but only a small proportion of cases ever require surgical intervention. He emphasized the fact that internal medication, either alone or combined with surgical measures, must be instituted before a radical cure could result.

#### The Gall-Bladder.

DR. J. LIVELY JOHNSON, Louisville, discussed diagnosis and treatment of gallstones. The medical treatment was mentioned only to call attention to its utter inability to remove gallstones either by expulsion or dissolving. Specific diet is unimportant. Operation is indicated as soon as diagnosis is made.

#### The Surgical Treatment of Cholelithiasis.

DR. DAVID BARROW, Lexington, read this paper. Surgical treatment should be resorted to where, 1. the colics are frequent, or the suffering is severe, and of several days' duration; 2. where there is evidence of cystic or common duct obstruction, not positively due to malignant disease; 3. in some cases of positive malignancy with the hope of lessening pain and discomfort, and to remove the stones frequently present in these cases, or to do a cholecystenterostomy for the relief of cholemia; 4. in acute infection of the gall-passages, cholecystitis and cholangitis; 5. in chronic infection of the gall-passages, as manifested by irregular chilliness and evening temperature, with loss of flesh, weakness and partial invalidism, with previous history of indigestion and colic; 6. in a chronically distended gall-bladder large enough to be felt through the abdominal parietes; 7. in intestinal obstruction due to gallstones in the intestine or to inflammation caused by gallstones; 8. in some obscure inflammation pointing to trouble in the upper right side of the abdominal cavity. Results from primary operation are usually satisfactory. If secondary operation becomes necessary, the gall-bladder should be removed where possible.

#### The Treatment of Biliary Colic.

The next paper was read by DR. EDWARD SPEIDEL, Louisville. The author laid stress upon colon injections of hot saline solution.

DR. F. C. WILSON, Louisville, said, unquestionably some cases could be relieved by medical means, while others required the surgeon's knife.

DR. W. A. QUINN, Lexington, thought the medical treatment of gallstones a delusion.

DR. T. H. STUCKY, Louisville, thought perhaps the proposition should be reversed, i. e., instead of the medical man turning all these cases of gallstones over to the surgeon, the surgeon should refer such cases to the general practitioner. He believed, however, that it was absolutely impossible to draw the line where the medical man should leave off and the surgeon commence. He emphasized the efficacy of high rectal enemata of hot saline solution.

DR. A. T. McCORMACK, Bowling Green, said the treatment in many cases of gallstones should be purely medical, that they never required surgical intervention; on the other hand, there were many cases distinctly surgical, and operation should be done promptly.

DR. J. V. PREWITT, West Point, referred to a case in which manipulation under chloroform had resulted in passage of gallstones by the bowel and complete recovery.

DR. LOUIS FRANK, Louisville, said that not infrequently there was adhesion between the gall-bladder and duodenum, or some other part of the intestine, followed by ulceration and perforation, allowing gallstones to pass into the bowel, and the physician attributed the passage of such stones to medical treatment. He emphasized the importance of surgical intervention and drainage as soon as diagnosis is made. Gallstones are undoubtedly due to bacterial infection.

DR. A. SCHACHNER, Louisville, said, as soon as diagnosis is made, surgery should be resorted to for removal of the gallstones and establishment of drainage.

#### Nasal Obstructions.

At the afternoon session, May 8, DR. DUDLEY S. REYNOLDS, Louisville, read a paper on this subject, and reported illustrative cases resulting from foreign bodies, polypi, etc., with treatment instituted. He uses adrenalin for reduction of swelling of nasal mucous membrane in order to make a differential diagnosis between abnormal bone growths, ordinary neoplasms, foreign bodies, pharyngeal growths, etc.

DR. WM. CHEATHAM, Louisville, spoke of the dangers of secondary hemorrhage following use of adrenalin and cocaine in the nasal passages. Where obstruction due to engorged tissues, he believed constitutional treatment important. Local treatment with cauterization is not effective in many cases.

DR. M. F. COOMES, Louisville, thought secondary hemorrhage following use of adrenalin and cocaine in the nasal passages was due to carelessness on part of the physician, and referred to two such cases.

#### Chancre of the Tonsils.

DR. WILLIAM CHEATHAM, Louisville, reported seven such cases and thought many cases were overlooked.

#### The Mammary Gland—A Plea in Equity.

The next paper was read by DR. C. C. LEWIS, Owensboro, urging that physicians should educate mothers to nurse their infants at the breast wherever possible, rather than to feed them upon any of the artificial foods, which is an evil that is constantly growing and should be checked.

#### Suggestion: Factory Surgery: X-Rays.

DR. ANNA G. SEDAM, Covington, read a paper on "Suggestive Therapeutics, or Psychologic Medicine."

"The Hand in Factory Surgery" was the subject of a paper by DR. C. C. GODSHAW, Louisville.

The next paper, "The X-Rays in Surgery," was by DR. A. T. McCORMACK, Bowling Green.

DR. J. B. KINNAIRD, Lancaster, followed with "The Therapeutics of the X-Rays."

#### Medical Management of Appendicitis.

This paper was read by DR. JOSEPH W. IRWIN, Louisville. The author said that in the last 29 years he had seen and treated upward of 150 primary cases of what was then known as perityphlitis, later and now as appendicitis, without having to resort to surgical means, and had to record but two relapses, both patients surviving, and a single death.

#### Intestinal Obstruction, with Report of Cases.

DR. AUGUST SCHACHNER, Louisville, reported several interesting and instructive cases and advised use of the needle and thread versus mechanical devices.

#### Election of Officers.

On the third day, May 9, the following officers were elected: President, DR. W. W. RICHMOND, Clinton; vice-presidents, Drs. C. C. LEWIS, Owensboro, and J. D. WELLS, Cynthiana; permanent secretary and treasurer, DR. STEELE BAILEY, Stanford; librarian, DR. F. L. LAPSLEY, Paris; delegates to the American Medical Association, Drs. J. N. McCORMACK, Bowling Green, (two years), and Thomas Hunt Stucky, Louisville (one year).

#### The New Constitution.

The following report of committee on revision of the Constitution was read and adopted by unanimous vote:

"The committee composed of one member from each of the counties represented at this meeting of the Kentucky State Medical Society, having with great care and patience read and considered the instrument submitted to them, beg leave to recommend its adoption by the Kentucky State Medical Society. Your committee arrived at this conclusion after due deliberation, and by unanimous vote. (Signed) John G. Cecil, M.D., Chairman."

#### Concluding Papers.

DR. H. T. RIVERS, Paducah, read a paper entitled "Continued Fevers of Southwestern Kentucky."

DR. GEORGE R. RAU, Louisville, presented a paper on the subject of "Paralytic Dementia."

DR. J. N. McCORMACK, Bowling Green, escorted the newly elected president to the chair, and DR. RICHMOND then delivered an appropriate and impressive address.

DR. JOHN A. LEWIS, Georgetown, was selected to deliver the annual address in surgery, and DR. JOHN G. CECIL, Louisville, was selected to deliver the annual address in medicine, at the next meeting. The Society adjourned to meet in Louisville in May, 1903.

#### TORONTO CLINICAL SOCIETY.

*The Final Meeting of the Session 1901-1902, held May 7, 1902.*

#### Fatal Membranous Glossitis.

DR. A. J. HARRINGTON reported an unusual case of membranous glossitis, of which he stated he could find no trace in the literature. The specimen was presented. The condition occurred in an infant of eleven months of age, a fine, healthy, robust child. It had measles in March, 1902. On April 8 the whole cast of the tongue exfoliated, and the system of the child was thoroughly saturated with sepsis. The child died the following morning.

#### Epidemic of Mumps.

DR. ALLAN BAINES reported a very severe case of metrorrhagia in a young girl of sixteen, following mumps. This brought up a discussion on mumps, of which there has been an epidemic in Toronto during the past two or three months. Several members referred to cases of the disease confined to the submaxillary glands alone. DR. FRED. FENTON reported favorably on the use of urotropin in pyuria, having found it especially valuable in old men with enlarged prostates and residual urine. DR. C. J. O. C. HASTINGS reported three cases of myxomatous degeneration of the villi of the chorion which he had had in his practice. All recovered.

#### Election of Officers.

The following were the officers elected for the ensuing year: President, DR. E. E. KING; vice-president, DR. GEORGE McDONAGH; corresponding secretary, DR. W. J. McCOLLUM; recording secretary, DR. GEORGE ELLIOTT; treasurer, DR. GEOFFREY BOYD; executive committee, Drs. J. F. W. ROSS, J. ORLANDO ORR, H. A. BRUCE, H. C. PARSONS and J. T. FOTHERINGHAM. On the evening of April 15, the annual dinner of the society was held at the Toronto Club, and a most enjoyable time spent.

## NORTH BRANCH OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY.

*Regular Meeting, held April 17, 1902.*

The President, Dr. A. M. Eaton, in the Chair.

### Microscopic Diagnosis of the Abnormalities of the Blood.

DR. W. WAYNE BABCOCK read this paper and stated that there were four things to be considered in this connection: 1. the amount of hemoglobin; 2. the number of red blood corpuscles; 3. the number of white corpuscles; and 4. the determination, by a method of staining and microscopic examination, of the shape and quality of the corpuscles. The estimation of the hemoglobin by the use of the Talquist scale was thought to give sufficiently correct results for general purposes; where more accurate results were required the Gower's instrument was recommended. For general use in estimating the corpuscular richness of the blood the Oliver instrument was recommended, and when a more accurate result is desired, of course, recourse will of necessity be had to one of the counting methods. Dr. Babcock gave some of the details of technique and illustrated the use of the knowledge to be gained by these observations.

### The Use of Simple Microscopic Methods by the General Practitioner.

DR. ROBERT L. PITFIELD urged the more general use of the microscope to confirm clinical diagnosis, especial attention being directed to tubercular involvement, nephritis, diphtheria and venereal disease. Numerous cases were cited where the diagnosis of tuberculosis was established solely by the microscope. The reader expressed the opinion that about 72 per cent. of the cases of diphtheria and tonsillitis could be correctly diagnosed by the examination of a simple smear from the throat discharge. While the use of the culture was recognized as a more certain method, it was thought that the latter procedure was beyond the reach of the average practitioner. The value of the examination of stools was also commented upon.

### Discussion.

The discussion was opened by Dr. Judson Daland, who believed that Fleisch's hemometer, modified by the little slit cap, was the best method of estimating the amount of hemoglobin. Dr. Daland had given considerable attention to the examination of fresh blood and did not feel that this was practiced to as great an extent in this country as might be desirable. In his opinion, much valuable information could be obtained by observing the manner in which crenation and rouleauxing take place and the manner in which the fibrin is formed. It is possible to conduct the examination for from 25 to 30 minutes before crenation interferes. The speaker cited a case which had recently come under his observation presenting all the physical symptoms of pulmonary tuberculosis, but in which the sputum, although frequently examined by different observers, showed no tubercle bacilli. The case eventually proved to be one of aortic aneurysm.

D. FREDERICK A. PACKARD remarked upon the contrast between the present laboratory methods and those in vogue about twenty years ago. Attention was directed to the importance of the examination of the stools; especially was this thought to be important in cases of children who were supposed to be suffering with worms. The liability of error in making the diagnosis of Bright's disease solely upon the presence of albumin and casts in the urine was commented upon and the importance of considering these factors in conjunction with the clinical symptoms was remarked. Where albumin is persistently present in the evening urine and absent or present in a very much smaller amount in the morning specimen, it was thought to suggest either stone in the kidney or movable kidney.

DR. JOSEPH SAILER emphasized the importance of microscopic examinations in differentiating diseases due to the colon group of bacteria and attention was called to the regularity with which cholera is diagnosed by this method in the Orient.

DR. AUGUSTUS A. ESHNER considered that in cases where albumin and casts are present in a patient's urine, a distinction should be made between the cases in which they are con-

stantly present and those in which the condition is transitory; in the latter instance he feels that but little importance should be attached thereto. In regard to the estimation of the corpuscles in the blood, the speaker stated that his experience had been principally with the Thoma-Zeiss instrument. For ordinary purposes he considered that not only can one estimate the number of red cells, but can also form an approximate idea of the number of white corpuscles by the use of this instrument. In cases where diphtheria is suspected, the speaker stated that he believed it was just as important to examine the nasal discharges as it was to examine the exudates from the throat, as in his opinion nasal diphtheria is not so rare as is sometimes supposed.

DR. M. H. FUSSELL spoke of the great value to be derived by the general practitioner from the examination of the urine of his patients, as in his opinion many cases of Bright's disease and other affections are not recognized until it is practically too late to be of any service to the patient, when the physician depends entirely upon the clinical symptoms. The sputum should be examined in every chronic cough, even although the physical signs of tuberculosis did not happen to be present. In the examination of the exudates from the throat for the diphtheria bacillus, he felt that cultures are far more accurate than the microscopic examination of a simple smear of the discharge on a cover glass, and he does not feel that it is safe to exclude the disease even although a negative result is obtained by the latter method.

## CALIFORNIA ACADEMY OF MEDICINE.

*Monthly Meeting, held April 29, 1902.*

DR. D. W. MONTGOMERY in the Chair.

### Fracture of Vertebra.

DR. T. W. HUNTINGTON presented a case of fracture of a spinal vertebra treated on the expectant plan. There was a slight prominence, a slight deviation and some rigidity; no paralysis; no serious disturbance of functions of rectum or bladder; some anesthesia; patellar reflexes were normal. Extension was used, and at the end of forty-eight hours evidence of displacement had disappeared. He also gave history of another case with similar symptoms and treatment, who was wearing at present a plaster cast. Both patients had done well.

### New Method of Prostatectomy.

DR. GEORGE GOODFELLOW presented a paper on "Perineal Prostatectomy," giving a technique which he believed he was the first to deliberately plan and execute. With the patient in the lithotomy position, the bladder being empty or full as the case may be, a lithotomy staff is introduced, the legs then elevated somewhat, a median incision from the base of the scrotum to the margin of the anus is made and carried to the membranous urethra, which is entered with a lithotomy knife and the opening extended into the bladder. The finger is then introduced, the staff removed and the legs, which were somewhat elevated, are flexed on the abdomen and thorax to as great an extent as possible and with the opposing hand over the hypogastrium the bladder is depressed and the enucleation, beginning at the beak of the prostate below and working upward next to the bladder, is carried on, the time consumed for complete enucleation rarely being over five minutes, the resulting hemorrhage virtually nothing. The gland may be removed entire or lobe by lobe. If the bladder has been full of pus, sometimes it was washed out. No drainage of any kind was made, the perineal incision sufficing. In his earlier cases the practice was to pass straight sounds through the perineal wound into the bladder every other day for a week or more to keep free drainage, and in any complicated case such a course might be adopted; but of late it had not been found needful. In all recent cases no instrumentation of any kind has been permitted, neither irrigation, passage of sounds nor catheters, and all had done as well or better than under the older process. The points he wished expressly emphasized were the position of the patient, and the incision into the bladder; to these he thought were due his unvarying success.

Dr. D. W. MONTGOMERY presented a case of epithelioma of the upper lip, which the x-ray treatment failed to check. Dr. H. M. Sherman therefore removed the entire upper lip, by incisions which extended directly upward from the corners of the mouth and then were joined by a horizontal incision close to the alae and septum of the nose. Flaps consisting of all the tissues of the cheek were brought together in the place of the removed lip. At present the lip is a perfectly serviceable one and is not unsightly.

#### ASSOCIATION OF AMERICAN PHYSICIANS.

*Seventeenth Annual Meeting, held in Washington, D. C., April 29 and 30, 1902.*

President, Dr. J. C. Wilson, Philadelphia, in the Chair.

*(Concluded from p. 1325.)*

#### Splenic Anemia and Its Varieties.

Dr. OSLER, in this paper, discussed the general question of splenic anemias, but paid particular attention to one group of cases which he thought could be separated from the general class as a distinct type. The particular features of this group are the chronicity of the anemia and splenic enlargement. Secondly, the absence of any enlargement of the lymph glands. Thirdly, the blood changes are those of chloro-anemia, the red cells in some cases being above 4,000,000, while the hemoglobin is as low as 30 per cent. and in some of the cases there is an exceedingly low leucocytic count. Fourthly, pigmentation of the skin is sometimes a characteristic feature, being mottled in some cases and in others resembling argyria. Fifthly, in the late stages the liver is involved and cirrhosis has been found postmortem.

Dr. Osler thought that this group with the symptoms referred to was quite distinct from the cases of pernicious anemia with enlarged spleen, from certain cases of cirrhosis of the liver, particularly syphilitic forms, and from Hodgkin's disease. The name of splenic anemia was used simply for the want of a better one. Treatment of these cases is not very satisfactory. There may be improvement for a time and the red cells increase in number, but the hemoglobin remains low. The nature of the disease is unknown. Whether due to the spleen or not is unsettled, but some cases have recovered after removal of the spleen. With the aid of other members of the association Dr. Osler had collected 42 cases of this character.

Dr. MUSSEY opened the discussion and reported two cases of this character. He did not believe they should be considered as a separate disease.

Dr. BILLINGS reported two cases, one of which followed a severe hemorrhage.

Dr. CABBOTT said that he had seen eight cases that followed the type presented by Dr. Osler, but he was not convinced that these cases should be grouped under a separate special heading.

Dr. STYLES of the Agricultural Department asked if any of these cases had been subjected to intestinal examinations to exclude the presence of the strongyloides or the uncinariæ americanæ—both of which have been found in cases of anemia with enlarged spleen.

Dr. H. F. VICKERY reported "A Case of Albumosuria Associated with Pernicious Anemia."

#### A Report of the Cases of Thermic Fever Treated at the Pennsylvania Hospital in the Summer of 1901.

Dr. M. J. LEWIS read this paper. There were 91 cases of thermic fever seen at the Pennsylvania Hospital during the hot weather of July, 1901, which showed a temperature of 100 degrees F. and over. There were 31 females and 60 males. The temperature of the patients varied from 100 to 113 degrees, no patient with a temperature of under 106 dying and no case with a temperature of 111 or more recovering. The cases with very high temperatures usually showed convulsions with retraction of the head. Examinations of the urine showed nothing special beyond the presence of slight amounts of albumin and sometimes casts. Blood examinations were made in seventeen cases, but with such varying results that it was impossible to draw any valuable conclusions. Milder cases were treated with rest in a cool portion of the ward, the application of an ice

cap and stimulants. The more severe cases were treated in a large open tent containing two large electric fans and movable bath-tubs. In a few cases the hose was employed to direct a stream of water from a distance over the patient's body. Rubbing the body with ice seemed to be easier and more satisfactory than the use of the tub. The advisability of bleeding as a routine practice was discountenanced and the intravenous injection of normal saline solution strongly endorsed.

In the discussion Drs. Billings, Musser and Packard all related their experiences during the past summer and advocated the use of saline injections.

#### Hemolymph Glands.

At the evening session, in the absence of Drs. Dock and Warthin, Dr. Flexner presented their lantern slide demonstration of the hemolymph glands. Dr. Warthin found these glands extremely numerous, but difficult to distinguish from ordinary lymph glands because after death the blood leaves them to a great extent. He estimates that in the human subject they bear about the ratio of one to ten ordinary lymph glands. Dr. Flexner believed that the most valuable part of his work, however, was to be found in the consideration of the histologic structure of these glands. He separates them into two classes, one following the general type of the spleen and for the other the bone marrow might be taken as the type. They all contain structures similar to the ordinary lymph glands with the additional features peculiarly their own. The trabecular spaces were filled with blood and throughout the whole of the gland there is a reticulum containing spaces lined with spindle cells and filled with blood. The glandular areas resemble the Malpighian bodies of the spleen except that only very rarely can a vessel be found comparable to the branches of the central splenic artery. He was not able to find evidences of blood formation in these glands, but on the contrary, found evidences of blood destruction. In the marrow type he found in addition to these peculiar appearances the presence of fat globules or spaces from which fat had been absorbed. He thinks they have nothing to do with blood formation under normal conditions, but that under pathologic conditions they may act quite vigorously to assist in the formation of blood.

Dr. C. S. BOND exhibited lantern slides showing the presence of mitosis in the circulating blood.

Dr. FRANK BILLINGS gave a demonstration of sections showing the anguillula aceti obtained from a specimen of urine.

Dr. JAMES EWING exhibited some slides showing the blood changes in some smallpox cases. He had been studying particularly the development of the so-called vaccine bodies. He was inclined to think these bodies are always the result of the fragmentation of red corpuscles.

#### Pleurisy with Effusion.

At the Wednesday morning session the first paper presented was that by Dr. Richard C. Cabbott on "The Prognosis of Pleurisy with Serous Effusion." He had carefully sought out the three hundred patients treated for serous pleurisy at the Massachusetts General Hospital during two decades. He succeeded in finding either by letter or a personal visit 152 of these patients who had been discharged apparently recovered. Considering their conditions when treated and their progress after dismissal from the hospital he concluded, first, that 80 per cent. of the cases of uncomplicated serous pleurisy are in good health after 5 years or more (more than half of his cases had been followed more than 10 years); second, 90 per cent. are apparently in full health at the end of from 2 to 5 years—that is, the pleurisy has no immediate connection with any other affection; third, 15 per cent. of the cases have sooner or later developed tuberculosis, but in only 3 per cent. has this manifested itself within 2 years of the date of pleural effusion; fourth, the type of tuberculosis was, as a rule, mild and of slow course; nevertheless, a very rapid form of tuberculosis may develop many years after the pleurisy. Of those who develop tuberculosis more than two-thirds presented tuberculous family histories.

His figures tended to prove that whether pleurisy means tuberculosis or not the outlook is bright provided no family

history of tuberculosis clouds it. If pleurisy means tuberculosis it is a very mild form and usually yields to proper treatment.

DR. OSLER expressed the thanks of the association to Dr. Cabbott for his great labor in securing such statistics and said that they proved that pleurisy with effusion is not such a grave matter as it has always been considered.

DR. HARRIS of Manchester, England, stated that the practice in England was based upon figures much more unfavorable than these. Life insurance companies there, as a rule, declined to accept any applicant who has had pleurisy within five years. He thought these rules were probably too strict and that Dr. Cabbott's figures would cause a reconsideration of the prognosis in this disease.

DR. JACOBI stated in support of Dr. Cabbott's figures the fact that it is so very common when examining healthy patients, or patients who complain of some other trouble, to find the evidences of an old pleurisy.

#### Empyema.

DR. CHARLES F. WITHINGTON read a paper entitled "A Clinical Study of a Hundred and Thirty-five Cases of Empyema based Upon the Bacteriologic Findings in the Exudate."

DR. OSLER asked whether the author had found any great increase in the number of cases of pyemia following pneumonia during the past five years. It was reported to be so by Dr. White of Guy's Hospital and Dr. Osler had had the same experience at the Hopkins.

Dr. Withington replied in the affirmative.

#### Spontaneous Non-tuberculous Pneumothorax.

DR. M. H. FUSSELL gave the definition as "a pneumothorax occurring suddenly in healthy individuals, without the cause being discoverable by physical examination or by the history of the case and in which there is no formation of liquid." Dr. Fussell reported in detail the histories of two cases and reviewed the literature of the subject. He finds that aspiration is a certain and safe means of relief and should be resorted to in severe or prolonged attacks. He believes this form of pneumothorax to be benign since all but one of the reported cases have recovered.

Drs. Kinnicutt, Cohen, Shattuck, Janeway, Peabody, Osler and Billings reported cases.

#### Some Pulsations in the Chest Other Than Aneurysmal.

DR. A. R. EDWARDS reported a case of pernicious anemia in which there was a diffuse expansile pulsation in the chest and upper abdomen and a second case in which there was a sarcoma of the lungs with pulsation. The first case presented many symptoms of aneurysm, but autopsy examination failed to disclose any anatomic explanation for these symptoms.

DR. LAFLEURE remarked that within the past two months he had had a similar experience: the case was one of secondary anemia and the phenomena those usual for aneurysm, but the autopsy showed an ulceration of the stomach which had not been previously recognized.

#### Healed Ulcerative Endocarditis.

DR. J. B. HERRICK stated that we might, *a priori*, expect occasional recovery in ulcerative endocarditis and that a review of the literature shows that such occasional recoveries do occur.

#### The Condition of the Heart in Pregnancy.

DR. ALFRED STENGEL read a paper to show that the supposed hypertrophy of the heart is in most instances due simply to the dislocation of the apex. He thought the murmur so frequently heard in the later months is due to distension of the right heart and the conus arteriosus. He could find no change in the blood pressure before and immediately after delivery.

DR. F. P. KINNICUTT read "A Case of Pancreatic Lithiasis with Recovery of the Characteristic Calculi from the Stools. Followed by an Attack of Cholelithiasis a year later with the Passage of Characteristic Biliary Calculi."

DR. S. SOLIS COHEN read "A Further Contribution to the Subject of Vasomotor Ataxia."

DR. HENRY JACKSON read: "Intestinal Hemorrhage: Its Relation to Duodenal Ulcer."

#### Prognosis and Treatment of Tuberculous Peritonitis.

DR. F. C. SHATTUCK presented an analysis of 98 cases of tubercular peritonitis treated in the Massachusetts General Hospital between 1889 and 1900, with special reference to the treatment. This was divided into purely medical treatment, tapping for the relief of effusion and surgical measures. Treatment by surgical means seemed to secure better results than by purely medical remedies.

#### Some Clinical Manifestations of Hepatic Cirrhosis in the Light of Eighty Autopsies.

DR. G. G. SEARS said persistent jaundice and hemorrhage from the digestive tract seldom occurred until the connective tissue formation had well advanced. Hemorrhage was found to be almost invariably due to some gross lesion which in most cases was an esophageal varix. Ascites was also a late symptom and its early appearance was usually due to other conditions than simple portal obstruction. Degenerative changes in the heart and probably in the vascular system were contributing factors. Continuous fever was never found except with complications. No evidence was found to show that the course of the disease is not always progressive. Operative treatment is indicated in a very small percentage of cases and it is doubtful whether it is any more effective than early and persistent tapping.

#### Clinical Manifestations of the Early Stage of Cirrhosis of the Liver.

DR. FRANK BILLINGS presented an elaborate consideration of this subject with the presentation of cases to illustrate the points brought out. It will appear in this journal.

#### Experimental Glycosuria.

DR. C. A. HERTER read a paper on "Experimental Glycosuria from Adrenalin Chlorid and Its Relation to other Forms of Glycosuria dependent on the action of Reducing Substances on the Cells of the Pancreas." Evidence was brought forth to show that many and probably most forms of glycosuria and diabetes are due to the action of substances or conditions which interfere with normal oxidations in the cells of the pancreas.

#### Election of Officers.

The meeting closed with the election of the following officers for the ensuing year:

President, Dr. James Stewart; vice-president, Dr. W. T. Councilman; secretary, Dr. Henry Hunn; treasurer, Dr. J. P. Crozer Griffith; recorder, Dr. S. Solis Cohen; councillors, Drs. Chas. G. Stockton and Walter Reed.

#### THE CHICAGO LARYNGOLOGICAL AND CLIMATOLOGICAL ASSOCIATION.

*Regular Meeting, held April 21, 1902.*

The President, Dr. Moreau R. Brown, in the chair.

*(Concluded from p. 1324.)*

#### Fibro-sarcoma of the Soft Palate and Tonsil, with Exhibition of Pathologic Specimen.

DR. CHARLES M. ROBERTSON narrated the case of C. S., a farmer by occupation, aged 62, who, while picking his teeth with a straw, pricked the left tonsil, causing only slight pain. In a few days he noticed a small swelling above the left tonsil, which increased rapidly in size till the end of eight weeks, when he presented himself for relief. At this time the patient experienced great difficulty in breathing, and it was almost impossible to swallow food. Upon examination, a large tumor was found occupying the left palatal arch, well down to its base, involving the tonsil and side of the pharynx as far as the epiglottis, and up behind the edge of the hard palate as far as the left Eustachian tube. It extended forward into the mouth to within one inch of the incisor teeth. The growth was smooth in contour, lighter in color than the surrounding tissues, and firm and elastic to the touch. Under cocaine, a piece of the growth was removed for microscopic examination and pronounced fibro-sarcoma. The following week the growth was removed under chloroform anesthesia. It was found to be en-

encapsulated, and on this account a favorable prognosis was made. In looking over the literature I find some 25 cases reported of sarcoma of the soft palate and 45 additional cases of sarcoma, where the soft palate and tonsil or tonsil alone were involved. In nearly all the cases the growth was removed by external operation and in these cases recurrence was frequent, whereas the encapsulated growths removed by the mouth were not so prone to recurrence. The case under consideration has as yet shown no signs of new growth, twenty months having elapsed, and therefore I feel justified in reporting it as a cure.

DR. E. FLETCHER INGALLS recalled the case of a boy of 13, upon whom he operated and removed a fibro-sarcoma in 1883, through the natural passages. The tumor soon showed a tendency to recurrence, but as the patient was in the city alone and fell into bad company, I was obliged to send him to his home in a distant state. He came to see me again sixteen years afterward for pain in the chest, apparently of rheumatic origin. He stated that after returning to his home the first time the tumor had grown so as to cause complete nasal obstruction, and great prominence of the right cheek, and to destroy sight in right eye, but after a few years it had almost completely disappeared by atrophy.

#### Carcinoma of the Epiglottis.

DR. A. M. CORWIN gave the history of a man 66 years old, whose present wife has pulmonary tuberculosis, which has been manifested in its various stages even to marked cavity formation. Her brother, who died of tuberculosis, resided at this patient's home during a long illness. The patient has been of robust health up to recent years. There is no history or evidence of syphilis. His family history is excellent. About three months ago he consulted the writer for an uneasiness which he had noticed for three months in the lower part of the pharynx, a slight feeling of fulness, stiffness and increased secretion, which required frequent clearing of the throat. There was little or no pain except some dysphagia which began about six weeks before. His voice was clear and he had no cough. Examination showed nose and fauces normal. The epiglottis was slightly congested, but not swollen or otherwise abnormal except along its left margin from tip to base. Here there was a proliferative ulcerated surface, which projected above the normal surface of the epiglottis as a cauliflower-like formation covered by a grayish muco-purulent secretion. When this was removed by swab the surface was seen to be granular, though it did not bleed except after considerable violence. The side of the tongue and the adjacent wall of the pharynx, which were most of the time in contact with the growth, presented a similar granular ulcerated surface, which also involved the aryepiglottic and pharyngo-epiglottic folds. Considering the character of the morbid area and the extent of the surface involved, the absence of swelling of the neighboring tissues and the absence of glandular enlargement was noteworthy. The larynx and trachea were otherwise normal. Examination of the chest showed lungs normal and heart substantially so. Thorough examination of the sputum and scrapings of the epiglottis show absence of tubercle bacilli or other significant morbid elements. The local appearance, the duration, the absence of pain and lung and sputum findings, lack of emaciation, normal temperature and pulse ruled out tuberculosis. The administration of iodids was continued several weeks without benefiting his throat in the least. The case is therefore one of malignant trouble (carcinoma). A small piece from the diseased area was so small as to be unsatisfactory in demonstrating carcinoma tissue. There seems to have been slightly more rapid degeneration of the point of removal so that I have considered that nothing would be gained by further antimortem histologic investigations because of the contraindications to radical operation in the case, because of the extent of involvement, the age of the patient, his arteriosclerosis, his chronic nephritis and epilepsy. A good specimen will be obtained postmortem. The progress in the last three months has been slow, and it is about an eighth worse than when I first saw him, two and a half months ago. He has been upon a forced milk diet with starchy foods judiciously chosen, and nitrogenous food avoided. It is somewhat remarkable that

he has retained his weight. Local measures have been chiefly directed to cleanliness.

DR. OTTO J. STEIN narrated a case of leukoplakia buccalis and epithelioma treated for four months by x-rays with no benefit.

#### Resection of the Superior Maxilla.

DR. WILLIAM E. CASSELMERBY showed a case in which an unilateral resection of the superior maxilla had been made on account of intranasal fibro-sarcoma, presenting the patient chiefly to demonstrate the degree of deformity resulting. The incision was made from below the orbit around the nose and through the lip, the flap dissected back, and the left maxilla, including the teeth, removed. The man's cheek, however, still has a reasonable prominence. Union has failed along the line of the cleft in the hard palate, so that the patient practically now has an acquired cleft palate.

The situation of the growth and a shadow on translumination led me to think the antrum was involved, and this was one reason why resection of the superior maxillary bone was decided on. When we came to shell the growth out, it was disclosed that the antrum was not directly involved, but I am still of the opinion that the operation was justified by the appearance and character of the growth, but more so on the supposition that the antrum was involved. Had I been able to determine that the maxillary sinus was not affected, I would have advised a less extensive operation. There is, as yet, no definite evidence of recurrence, although the tissue which has partly filled in the space of the cheek bone does not look entirely natural.

Another hazard of the operation concerns the necessity of ligating the common carotid, or at least the external carotid artery, in order to control hemorrhage. Following the operation, this patient became paralyzed on the right side, and the paralysis has persisted somewhat, but it is gradually becoming less. Inasmuch as the line of ligature of the external carotid is very close to the common carotid, the paralysis might have occurred from a clot going through the common carotid as an embolus.

#### Concha Bullosa.

DR. GEORGE E. SHAMBAUGH presented a median sagittal section of a nose, showing a large bone cyst in the anterior end of the concha media. The cyst had thin, bony walls and was lined with smooth mucous membrane. It measured 28 mm. long and 25 mm. broad, and presented an empty, air-containing cavity, which communicated freely with the middle meatus, with the frontal sinus, with a large ethmoid cell pushed into the frontal sinus, and with the ethmoid labyrinth above and behind. The concha bullosa, or cystic enlargement of the concha media, is usually found as an empty, air-containing cavity, but occasionally it is found the seat of a mucocele or an empyema.

As a rule, it is not associated with any inflammatory condition, and the enlargement should be looked upon not as a pathologic product, the result of an inflammation, but as an anatomic variation, the result of a developmental anomaly.

#### Laryngitis Ending in Abscess.

DR. O. T. FREER presented two cases. The first was a woman upon whom he operated for an extensive cartilaginous and bony deflection of the nasal septum.

Dr. Freer then read the history of "A Case of Phlegmonous Laryngitis Terminating in Abscess in Front of the Larynx." The patient, aged 54, states that he never was ill until the beginning of this affection. After going to bed in perfect health on February 19, he awoke in the night with his tongue so swollen that he could not close his teeth. He felt a swelling in his neck near the larynx. He had severe dyspnea and could hardly speak. These symptoms continued until March 2, the stenosis slowly increasing. The attending physician found no fever. There was no chill or pain at any time. He could not swallow solids but could drink slowly; if he drank fast he had a coughing fit, the liquid entering his larynx. Examination, March 1, showed the region of the larynx filled by a large tumor-like mass from the hyoid bone to below the cricoid cartilage. The lump was soft in its center, pitted here on pressure and fluctuated obscurely. The lateral portions felt hard.

Palpation caused no pain. Laryngoscopy was impossible as the tumefied epiglottis was pulled down spasmodically by its depressors and touched the posterior pharyngeal wall, while its two sides folded together in the middle.

Suffocation seemed imminent March 2, so that I performed tracheotomy under cocain anesthesia. The abscess contained about two ounces of pus and was seated under the prelaryngeal muscles in front of the laryngeal cartilages. It had a tough, thick anterior wall. The abscess closed in a week and the tumor-like swelling slowly disappeared so that in three weeks the neck felt normal, but the laryngeal stenosis increased so that for some weeks the patient could draw no air at all through his larynx. Inspection showed great swelling of the aryteno-epiglottic folds and arytenoids, and this combined with retraction of the epiglottis made inspection of the deeper parts of the larynx impossible. The tracheotomy tube caused great irritation so that excessive amounts of mucus were coughed up. The swollen arytenoids continued to make swallowing difficult, but, March 19, the voice began to return. April 5 the cords could be seen and looked natural, but remained in a position of adduction, causing stenosis that made it impossible to remove the tube safely. The cords gradually separated so that on April 10 the tube was taken out. The laryngoscopic appearance was normal, but there was still a tendency to retraction of the epiglottis and adduction of the cords.

The history of this case is that of one of the varieties of erysipelatos or phlegmonous inflammation not uncommon in the region of the pharynx and larynx. The agents of septic inflammation enter the tissues through the lymph channels of the mouth and throat with well-known frequency. Whether the milder form or the phlegmonous inflammation ending in abscess will result, depends largely on the virulence of the infection, resistance of the individual and the formation of bubo. The infectious agent in nearly all instances is the streptococcus pyogenes.

The place of infection and direction taken by the septic matter in the lymph channels determines the site of the abscess, whether it will be a peri-tonsillar one, an angina of Ludwig, suppuration of the submaxillary glands, the carotid glands, a retropharyngeal abscess or, as in this instance, an abscess of the prelaryngeal and pretracheal space, called also the pre-visceral space, situated between the larynx and trachea and the muscles in front. In my experience abscess formation in this locality is not very rare. I have seen four cases within the last few years.

In the case which I present to-night the erysipelatos swelling of the laryngeal interior was either merely a part of the widespread inflammatory edema surrounding the deep-seated abscess in the neck, or the abscess was part of the phlegmonous erysipelas of the larynx.

The mildness of the symptoms shown by the patient is remarkable. The usual severe chill, high fever and prostration due to deep-seated phlegmonous processes were absent. The course also was unusually slow, as ordinarily tracheotomy is needed one or two days after the beginning.

The spasmodic retraction or depression of the epiglottis mentioned in the history was remarkable, and seemed to me to have some part in creating the dyspnea. I have seen the same position of the epiglottis in the form of a neurosis due to chronic nicotine poisoning. I have also seen it accompany acute laryngitis and disappear with it. The retraction seems to me due to reflex spasm of the thyro-epiglottic and aryteno-epiglottic muscles which pull down the epiglottis, cause it to fold in the middle and lie against the posterior pharyngeal wall. The depression may also be aided by spasm of the stylohyoid and thyrohyoid lifting the larynx towards the hyoid bone.

The adduction of the cords, in the patient shown this evening, proved to be due to reflex spasm of the adductors and not to posticus paralysis as I had at first supposed it to be, and it and the depression of the epiglottis improved as the laryngeal inflammation grew less. While the swelling was at its height it was impossible to exclude perichondritis of the thyroid or cricoid cartilages from the diagnosis, or to be sure that the abscess was not caused by suppuration due to their necrosis.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

### Atoxyl (Meta-Arsenous-Acid-Anilid).

Dr. Walther Schild, in the *Berliner Klin. Wochenschrift*, March 31, reports the results obtained from the therapeutic employment of a new arsenical preparation, atoxyl, containing 37.6 per cent. of metallic arsenic, about half as much as arsenous acid. It appears in the form of a white, odorless powder, of feebly salty taste, dissolving in water up to 20 per cent., though about 2 per cent. of crystals precipitate on cooling. On standing for some time the aqueous solution acquires a faint yellow tint, although decomposition does not take place; neither is this effected by boiling. Experiments on animals showed that the preparation was forty times less toxic than would be expected from the amount of arsenous acid it contains, and it is therefore twenty times less toxic than an equal amount of arsenous acid. In human beings administration of even small amounts by the mouth caused impairment of appetite, so that resort was had to subcutaneous injections. It was found that single doses representing 6 grains of the drug and also repeated doses of from 3 to 5 grains caused unpleasant effects, such as chilliness, vertigo, headache, irritability of the throat, but these subsided soon after withdrawal of the drug. Marked cardiac disease constitutes a contra-indication to the use of the preparation, inasmuch as it gives rise to palpitation of the heart and dyspnea even when administered in small doses. In the clinical employment of the preparation a 20 per cent. solution was used, and of this from 3 (gr. 3/5) to 15 minims (3 grains) were administered. The first five injections were given on successive days, and the remainder on alternate days. Seventy-five patients were thus subjected to treatment, receiving about 1500 injections without accident. Among the disorders from which they suffered are alopecia areata, dermatitis herpetiformis, cutaneous sarcomatosis, dermatitis exfoliativa chronica, xanthoma multiplex diabeticum, psoriasis, lichen ruber. In some cases topical applications were made at the same time, while in the remainder the injections constituted the sole medication. The results were entirely satisfactory, the drug being well borne and free from irritation and injurious effects, and the special advantage being the lesser frequency of administration.

### Laryngitis and Acute Bronchitis.

Lilgeois, in *Med. News*, prescribes the following mixture in treatment of acute attacks of laryngitis and bronchitis:

|                          |      |    |
|--------------------------|------|----|
| R. Sodii benzoatis ..... | 3ss  | 2  |
| Tinct. aconiti .....     | m. x | 60 |
| Aq. laurocerasi .....    | 3ss  | 2  |
| Syr. tolutani            |      |    |
| Syr. Codeinæ             |      |    |
| Aq. destil., āā .....    | 3i   | 30 |

M. Sig.: To be taken in divided doses in the twenty-four hours.

### Apomorphin in Hysteria and Epilepsy.

According to Faucher in *Ther. Month.*, apomorphin in doses of one-fifteenth to one-tenth grain is a rapid method of arresting an attack of hysteria or hystero-epilepsy and even an epileptic seizure. The vomiting which follows the injection and the subsequent depression soothes and relaxes the nervous system and controls the seizure. He states that it is a specific against attacks of hysteria, whatever form they may assume. The epileptic is usually inclined to eat too much, and the seizures frequently follow a heavy meal. The indications, therefore, are to relieve the digestive system and reduce the congestion of the nerve centers, both of which are promptly accomplished by apomorphin, although it is by no means a specific against epilepsy.

**Thrush.**

In young infants, thrush is frequently met by the general practitioner, especially in bottle-fed infants. W. J. Robinson of New York, in *Merck's Archives*, treats this condition with the following application, which, he states, is a never-failing combination.

|                                |     |    |
|--------------------------------|-----|----|
| R. Sodii hyposulphitis .....   | 3ss | 6  |
| or:                            |     |    |
| Sodii sulphitis .....          | 3ii | 8  |
| Glycerini .....                | 3vi | 24 |
| Aq. menth. pip. q. s. ad. .... | 3ii | 60 |

M. Sig.: Wrap a piece of absorbent cotton around the finger, dip into the solution and swab the mouth and tongue thoroughly.

This application should be repeated every half hour. No harm can result if the child should swallow some of the mixture. The efficiency of the foregoing solution is found in its chemical combination, as these salts liberate sulphurous acid gas or sulphur dioxide (SO<sub>2</sub>), a powerful antiseptic, while sulphur is deposited locally in a finely powdered state. He further states that in many cases of thrush the discharges are extremely acid; the parts about the anus become excoriated and cause the child further suffering. He then recommends internal treatment by mild alkalies and bismuth in the following combination:

|                              |      |    |
|------------------------------|------|----|
| R. Magnesie (calcined) ..... | 3ii  | 8  |
| Bismuthi subnit. ....        | 3i   | 4  |
| Syr. rhei arom. ....         | 3iii | 12 |
| Cord. anisi .....            | 3v   | 20 |

M. Sig.: One half to one teaspoonful three to five times a day.

Locally a drying powder should be frequently applied around the anal region. The following is recommended by him:

|                            |     |    |
|----------------------------|-----|----|
| R. Zinci oxidi .....       |     |    |
| Bismuthi subnit., aa ..... | 3ii | 8  |
| Lycopodii .....            | 3iv | 16 |

M. Sig.: Apply locally as a dusting powder.

**Cacodylic Acid in Diseases of the Skin.**

Saalfeld, as noted in *New York Med. Jour.*, states that he has used cacodylic salts in fifty cases of various skin diseases. The cacodylate of iron or sodium may be given internally in the form of pills containing four grains each, four times daily. A 5 per cent. solution may also be used, of which the dose is from ten to twenty drops, the maximum daily dose being forty drops. According to the author, the cacodylic salts are far superior to all the arsenic inorganic compounds in the treatment of skin diseases. He has never seen any disagreeable symptoms from their use. He has obtained excellent results with these drugs in the treatment of lichen planus rubra.

**Salicylic Acid for Soft Chancre.**

The following has been recommended by Szanto, according to the *New York Med. Jour.*, in the treatment of soft chancre:

|                           |        |    |
|---------------------------|--------|----|
| R. Acidi salicylici ..... | gr. xv | 1  |
| Tinct. benzoini .....     | 3ss    | 2  |
| Petrolati .....           | 3i     | 30 |

M. Sig.: Apply locally night and morning.

**Ichthargin in Gastric Catarrh.**

Ichthargin has been recommended in the treatment of gastric catarrh, dilatation and in gastric ulcer as follows:

|                     |        |     |
|---------------------|--------|-----|
| R. Ichthargin ..... | gr. ss | 103 |
| Aq. destil. ....    | 3viii  | 240 |

M. Sig.: One teaspoonful three times a day.

In the treatment of chaneroids it may be applied in the form of an ointment as follows:

|                          |            |    |
|--------------------------|------------|----|
| R. Ichthargin .....      | gr. xv     | 1  |
| Glycerini .....          | m. xv      | 1  |
| Aq. destil. ....         | gtts. viii | 50 |
| Petrolati q. s. ad. .... | 3ii        | 8  |

M. Rub well the silver salt with the water and glycerin and then add to the petrolatum.

**Diarrhea in Infants.**

N. S. Davis, in "Sys. of Physiologic Ther.," recommends in the treatment of diarrhea in infants due to over- or irregular

feeding or in bottle-fed infants, that all food be withheld for twelve or even twenty-four hours. The stomach should be cleansed by lavage if possible; if not, by a mild mercurial or castor oil. Sterilized water, and in the mildest cases a little egg albumin in water or barley water may be given to quench the thirst. Later, when the stools are less frequent and move natural, beef juice or thin mutton or chicken broth may be taken. Milk well diluted should be given after convalescence is established. Lime water is the best diluent. When excessive intestinal fermentation as well as diarrhea exists, a modification of milk is essential. If the stools have a sour smell and are acid in nature, the percentage of both sugar and fat should be lowered. If the odor is putrid the albumin should be lessened. All foods should be given in small amounts and often until convalescence is established.

**Carbuncle.**

The following combination, according to Dr. L. B. Young, in *Med. World*, gives great relief and checks the course of carbuncles:

|                               |        |      |
|-------------------------------|--------|------|
| R. Hydrarg. oxidi rubri ..... | 3i-3ii | 4-8  |
| Menthol .....                 | gr. xx | 1 30 |
| Pulv. camphoræ .....          | gr. xv | 1    |
| Cocainæ hydrochlor .....      | gr. x  | 65   |
| Acid. carbol. ....            | m. xx  | 1 30 |
| Morph. sulph. ....            | gr. v  | 30   |
| Vasellini .....               | 3i     | 30   |

M. Ft. unguentum. The menthol, camphor, cocain and carbolic acid should first be mixed together. The red oxid of mercury and the vaselin likewise mixed together, then mixed with the other ingredients. Sig.: Spread on sterilized gauze and apply, changing the dressing four or five times a day.

**As an Inhalation in Asthma.**

The following is recommended by the *Pract. Druggist* in the treatment of the attacks of dyspnea in asthma:

|                             |     |    |
|-----------------------------|-----|----|
| R. Gum benzoin .....        | 3ss | 2  |
| Pulv. jaborandi foliæ ..... | 3i  | 4  |
| Pulv. stramon. foliæ .....  | 3ii | 8  |
| Potassii nitratis .....     | 3ii | 8  |
| Carbo. ligni .....          | 3x  | 40 |

M. Sig.: To be ignited and the fumes inhaled.

The foregoing powder should be stirred with sufficient thin mucilage or tragacanth to form a stiff mass, then rolled into pencils and cut into pieces of suitable length. One of the pencils may be used at each treatment.

**Treatment of Lumbago.**

The *Practitioner* recommends the following as a local application in the treatment of lumbago:

|                          |      |    |
|--------------------------|------|----|
| R. Tinct. opii .....     | 3ii  | 8  |
| Aq. ammon. ....          | 3i   | 4  |
| Tinct. Cantharidis ..... | 3iii | 12 |
| Linimenti saponis .....  | 3x   | 40 |

M. Sig.: Apply locally with thorough friction.

W. J. Robinson recommends the following as a local application in articular rheumatism or lumbago:

|                            |            |      |
|----------------------------|------------|------|
| R. Camphor-chloralis ..... | 3i         | 4    |
| Acid. salicylici .....     | 3ss        | 2    |
| Menthol .....              | gr. xx     | 1 30 |
| Pulv. capsici .....        | 3i         | 4    |
| Ol. sinapis .....          | gtts. viii | 50   |
| Adipis lanæ .....          | 3iv        | 15   |
| Petrolati q. s. ad. ....   | 3ii        | 60   |

M. Sig.: Apply with vigorous friction.

**Acute Otitis Media.**

Macleod Yearsley, in the *Month. Cyc. of Pract. Medicine*, states, in an attack of acute middle ear inflammation, that the matter of first importance is absolute rest. The patient should be confined to his room, and if there is a likelihood of the case being of the suppurative type, he should be kept in bed. The ear should be protected from anything which is likely to increase the inflammation, and stimulating foods, alcoholic liquors, mental excitement and physical exertion must be forbidden. A large saline purge should be given. The pain can best be allayed by the application of heat or cold, or by the combination of the two. Heat may be employed dry by means

of the hot-water bag, hot flannels, or moist by instilling it into the ear. In using hot instillations a temperature of 115° F. will suffice. The continued influence of heat keeps the ear in a condition of congestion which retards resolution and favors the continuance of the inflammation, while the application of cold, especially to the parts surrounding the ear, often rapidly lessens the inflammation. The region below the auricle may be covered with cold compresses or an ice bag, and warm fluids may be instilled into the ear or hot sponges inserted. This has proved a useful method. But the best method of all is the application of leeches. From two to four or six, applied just in front of the tragus, will often cut short the pain and inflammation with rapidity. Their application should be followed by dry heat.

## Medicolegal.

**Statements to Physician Long After Accident.**—The Supreme Judicial Court of Massachusetts says, in the personal injury case of *Cronin vs. the Fitchburg & Leominster Street Railway Company*, that it is plain that the statement by a party to a cause of his bodily and nervous symptoms, made long after the occurrence of the accident to which he attributes them, and for purposes connected with the preparation for trial of a suit in which his condition of health is material, and not made to a physician for the purpose of obtaining advice for treatment, are not admissible in evidence in his own favor as proof of the matters stated. It is equally plain that every person admitted as an expert to testify to his opinion may state on his testimony the grounds and reasons for that opinion, and that the party calling the expert may put in evidence those grounds and reasons in the direct examination of the expert, and before calling upon him to give his opinion to the jury. In this case, where a physician made two examinations of the party suing for the purpose of testifying for him, and testified as to statements made by such party to him, there was no doubt, the court says, that the statements of the party were hearsay, and of that particularly dangerous and objectionable type—declarations of an interested party, made after suit brought, and for the very purpose of preparing evidence to be used in his own favor at the trial. But no such rule applied to them as that which excludes private conversations between husband and wife, or communications between attorney and client. They might be admitted in evidence if offered by the adverse party, either as admissions or as contradictions of the testimony of the person who made them. It followed that they might be admitted as the grounds and reasons of an opinion given in evidence, or to be so given, by an expert. Being admissible for that purpose, the exception to their admission was not well taken.

**Allowing Physician to Publish Article in Case.**—The first appellate division of the Supreme Court of New York takes a different view from that of the trial term on the question of the waiver of privilege in the case of *Scher vs. The Metropolitan Street Railway Company*. The action was brought to recover damages for personal injuries claimed to have been sustained by the party suing through the negligence of the company's servants in managing or operating a street railway car. The record showed that the party testified that, some 17 years before the accident occurred, he had suffered from serious illness in Germany for a period of about 7 years, during the greater part of which time he had been in a hospital, and confined to his bed. The company called as a witness a physician connected with a hospital in the City of New York to which the party resorted for treatment after the alleged accident. That physician was permitted to testify that he treated the party, who was suffering from a very rare disease, of so interesting a character that he was exhibited before a society of physicians at a public meeting, and an account of his peculiar disease was published by the witness in a medical journal; and he swore that the account was published with the party's knowledge and approval. Then, in the course of his examination, the witness was asked whether, prior to the preparation of the article published by him in the medical journal, the party told him that 17 years previously he had suf-

fered pains in the legs, lasting day and night, which forced him to stay in bed for 7 years. This was objected to on the ground that it was privileged. The trial term overruled the objection on the ground that the nature of the party's disease having been made public by his consent, the privilege was waived. But the appellate division thinks, under the authorities, that the communications made by the party to the physician were privileged, and there had been no waiver, even if the publication of the article and the public exhibitions were, as testified by the physician, though denied by the party, with the latter's full consent. It holds that, there being no waiver "upon the trial or examination," as provided by Section 836 of the New York Code of Civil Procedure, but, on the contrary, an objection made to the physician's violating the privilege, the ruling of the trial term admitting the testimony was clearly erroneous.

**Removal of Sponges—Skill Required of Surgeon.**—The Supreme Court of Georgia has affirmed a judgment in favor of the surgeon sued in the case of *Akridge vs. Geo. H. Noble*, an action for malpractice in which it was claimed that a sponge or pad which had been placed in the body of the party suing for the purpose of absorbing blood and pus while an operation was being performed had been carelessly left in the body after the wound had been closed, from which injury resulted. It holds that it was not error for the trial judge to charge the jury that, if they believed the pad or sponge had been in fact left in the body, they should then determine whether it was so left by reason of the failure of the surgeon to exercise due care and skill, and that he owed the party suing a duty to exercise reasonable care and skill in performing the operation; including in that expression not only the opening of the body and the removal of the affected parts, but also the use and handling of the sponges or pads. It says that the civil code of that state declares that a person professing to practice surgery must bring to the exercise of his profession a reasonable degree of care and skill, and that any injury resulting from a want of such care and skill will be a tort, or wrongful act, for which a recovery may be had. The reasonable and ordinary care, skill and diligence which the law requires of physicians and surgeons are such as those in the same general line of practice in the same general locality ordinarily have and exercise in like cases. The surgeon belongs to one of the learned professions, and he is required to bring to the exercise of his profession not only due care, but also due skill. "Skill," in the sense in which it is here used, includes not only the knowledge or information which the surgeon has in reference to the propriety or desirability of a given operation, but also the ability to perform the operation in a proper and approved way. And the court says that it must admit that it is unable to apprehend any clear distinction to be seen between the duty of the surgeon at the different stages of what, for want of a better term, it calls the "operation." It seems to it that the operation begins when the opening is made into the body, and ends when this opening has been closed in a proper way, after all appliances necessary to the successful operation have been removed from the body. From the time the surgeon opens with his knife the body of his patient until he closes the wound thus made, in a proper way, the law imposes upon him the duty of exercising not only due care, but due skill as well. During the entire time he must not only know what to do, but he must do it in a careful and skilful manner. The removal of pads or sponges from the body seems to require some degree of skill. It at least requires a surgeon to perform this service, and, if this is admitted, it is at the same time admitted that skill is required in the performance of the work. The court does not suppose that any one would contend for a moment that a surgeon would be authorized to leave this part of the work, even if not a part of the operation, or necessarily incident thereto, to any one who was not skilled in the science of surgery. The person seeking to remove sponges which have been placed in the human body must be possessed of the requisite knowledge and information to find where they may have been placed, or may have gone during the performance of the operation; and this knowledge or information on the part of the surgeon is what is called "skill." The removal of the sponges is a part of the operation; it is a part which requires the exercise of skill. But the surgeon here sued testi-

fied positively that he removed all of the pads; that he reached down in the cavity as far as he could reach, searched all over, and removed all of the pads; that he knew he got them all out, because he went thoroughly through the cavity, and found nothing there; that he was satisfied he had found all that were placed therein. In addition to this, the testimony of numerous surgeons was to the effect that, if a pad had been left in the body as claimed by the party suing, it would have resulted in her death within a short time after the operation had been performed, whereas she claimed that it remained in her body more than a year, and finally passed out of her body through the rectum, having passed into the rectum through a fistula which it had caused. The evidence, the court holds, fully authorized a verdict for the surgeon.

1. **New Species of Hookworm.**—Stiles reports and describes a new form of *Uncinaria* which differs from the *Uncinaria duodenalis*, chiefly in the absence of ventral recurved hook-like teeth, their places being taken by a pair of semilunar plates, somewhat similar to *U. stenocephala* of the dog. The species was found in a man at Galveston. It appears, therefore, that there are probably two species of hookworms contributing to the disease uncinariasis in man. This newly-described species is known to occur in Texas, Virginia and Porto Rico, which shows that we have here a special heretofore undescribed parasite causing the disease. This also indicates the practical correctness of the view that uncinariasis is endemic in the southern states, though rarely recognized.

4. **Intestinal Anastomosis.**—Two cases reported by Smith are commented on. In both the anastomosis was by lateral insertion of one end into the bowel, and he thinks there are several advantages in this method: "A better circulation is insured for each end of bowel. Each cut edge of mesentery is free to recover its circulation, eliminating the so-called 'dead space' at the mesenteric border which leads to leakage in end-to-end coaptation. At the site of the anastomosis a far better circulation is insured, because only the cut end of bowel has had its mesenteric circulation impaired. Danger of leakage is lessened, one end of the bowel, with dubious circulation and reparative power being closed so that simple peritoneal adhesive action will occlude it, and the other end entering bowel with normal reparative power. And there is less breaking strain from peri-

stalsis, I am inclined to think, because peristalsis in end-to-end anastomosis acts more vigorously on a new junction. The only serious disadvantage in the operation is found in the added injury to healthy intestine to insert the cut end of bowel. Again the blind end of bowel may develop fecal impaction as a minor disadvantageous possibility. I think the operation is indicated in cases of cancer, stricture, or other disease-producing obstruction of the bowel in the sigmoid and ileocecal regions. In a great measure this would render colostomy unnecessary, either through extirpation of the diseased area, or by short-circuiting the disease if inoperable. In gunshot wounds of the intestine with many perforations, in rupture of the intestine; in fact, in all conditions requiring anastomosis, when the circulation is dubious at the site of the bowel disease, this method of operation recommends itself."

5. **Palmar Reflex.**—Rhein has observed in a case of hemiplegia and in a case of disseminated sclerosis what he thinks is a new reflex. Slight irritation of the palmar surface of the hand with the point of an esthesiometer was followed by an extension of the hand and fingers. Sometimes only the hand was extended, and sometimes only one or more fingers. The arm was not drawn away in a manner analogous to the withdrawal of the foot when the plantar surface is irritated. He has not found a description of any such reflex in the literature and therefore offers it as a novelty.

7. **Mitral Obstruction.**—This is, as Satterthwaite remarks, apparently not a very uncommon condition, though well-marked mitral obstruction is somewhat rare. As a rule, it implies regurgitation, though this may occur without obstruction as in the earlier stages of organic insufficiency. In all cases of relative inefficiency, regurgitation is often primary to obstruction and subsequently its associate. Clinically, there is a close relation between them, but the prognosis of regurgitation is supposed to be rather better than that of obstruction. He reviews the diagnosis and symptoms, pointing out the difficulties in mitral obstruction. We have at first simply the signs of mitral insufficiency. Then when signs of regurgitation give way to those of obstruction, the right ventricle becomes hypertrophied and the impulse is thumping or strong. In a certain proportion of cases there is a thrill and a diastolic murmur, perhaps a presystolic and sharp "tapping" first sound at the apex. In the late stage when compensation fails the presystolic murmur disappears, because the auricle has no longer strength to drive its columns into the left ventricle. The right auricle becomes dilated through giving way of the tricuspid, causing pulsations in the veins of the neck. Dyspnea, dropsy and pulmonary apoplexy will then supervene. The following points are enumerated: "1. Mitral obstruction is usually fatal before the age of 40. 2. Females are little more prone to it than males. 3. There is apt to be a marked contrast between a strong cardiac impulse and a feeble radial pulse. 4. The true presystolic murmur occurred in 15 per cent. of my cases. It comes and goes, but is usually inaudible in the last stage. 5. It is apt to have a loud rasping or sawing quality, but may be 'gushing' or 'whirring.' It may also be faint or inaudible. 6. In about 40 per cent. there is some sort of diastolic murmur. 7. These murmurs are best heard over a rather limited area, somewhat oval in form, having for its center an area between the fourth left space, inside the nipple and the apex, and extending an inch or so to the right or the left. Occasionally this murmur is heard best as low as the fifth, sixth or even seventh left space; more rarely it is heard as high as the second left rib. 8. In 10 to 35 per cent. there was a thrill over this area. 9. The first sound at the apex is short and abrupt. 10. The second pulmonary sound at the base is usually intensified. 11. Occasionally a murmur with the second sound at the base is heard over the left auricular appendix. 12. At first there is hypertrophy of the left ventricle. Then atrophy of it, with hypertrophy of the left auricle; then follow dilatation and hypertrophy of the right heart. 13. Mitral insufficiency must to some extent accompany mitral obstruction. 14. In distinguishing the presystolic murmur of mitral obstruction from the Flint murmur of aortic insufficiency, we should rely on the 'long heart' and the strong impulse, or the 'Corrigan' of insufficiency, rather

than auscultatory signs. In case there is both aortic insufficiency and mitral obstruction a differential diagnosis is impossible, with the means we have now at our command."

8.—See abstract in THE JOURNAL of February 15, p. 472.

9. **Tendon Transplantation.**—Gibney reports and tabulates some 67 cases of tendon transplantation for various conditions, such as drop-wrist, talipes, dangle-leg, etc., and 7 cases of astragalectomy, arthrodesis and tendon transplantation. He finds altogether 92 patients were operated on and the final results ascertained in 67. Good results were obtained in 34 per cent., fair in 45 per cent., and negative in 21 per cent. "Taking, now, the deformities for which the operations were done, we have the following: Equino-varus 16, good 4, fair 9, negative 3; equinus 5 cases, good 1, fair 4; equino-valgus 22, good 10, fair 9, negative 3; calcaneo-valgus 10 cases; good 6, fair 3, negative 1; pure valgus 2 cases, good 1, fair 1; calcaneus, 1 case, fair result; dangle-leg 5 cases, negative 5; drop-wrist, 6 cases, good 1, fair 3, negative 2."

10. **Neurotic Questions in Tendon Transplantation.**—Collins points out that the chief point in the treatment of infantile cerebral palsy is the necessity of the differentiation of their causes, carefully distinguishing between those due to the gross destruction of tissues, as from hemorrhage and porencephaly, and palsies due to encephalitis and absence of development of the medullary sheaths as in Little's disease. In the latter cases there is often no real paralysis. The fixation and spasticity are the principal symptoms. If the patient could only send an impulse to make his motor apparatus work it would functionate, but there is the loss of the delicate co-ordinating or tonic-antagonistic impulses. One of the principles upon which the operation of tendon transplantation is advisable in these cases is to conduct an excess of innervation going to the muscles that are spastic, to the functional antagonists that are not, and to not only overcome the deformity produced by the former, but to add to the voluntary mobility of the part as well. The question of tendon transplantation for deformities resulting from anterior poliomyelitis are easier to answer satisfactorily. The motor nerve impulse depends upon its central mechanism and may by operation be switched from an extensor to a flexor muscle at will. It depends entirely on the track and on the apparatus to which it goes. There must also be developed a new muscle individuality which is the result of adaptation, not only of co-ordinating centers in the brain cortex, but in the peripheral parts as well. The sensory feelings in the part must be adapted in consciousness to the motor impulse, and he illustrates his ideas by diagrams. He thinks the field of applicability of tendon transplantation is wider than has been generally supposed and its use should be urged not only in the deformity of infantile palsy, but in similar deformities of the cerebral spastic hemiplegias and possibly also of spinal traumatic spastic palsies.

11. **Arteriosclerosis.**—Adler does not consider that Thoma's theory furnishes a complete and extensive explanation of all the facts of arteriosclerosis, at least in the smallest vessels and in the parenchyma. It is not impossible, he says, that definite local or systemic metabolic derangements can be conceived as a cause of indurative and degenerative lesions in blood vessels and connective tissue. Arteriosclerosis may be conceived as occurring in the smaller and smallest vessels and always and without exception associated with indurative processes in tissues and organs. It may begin in a single viscus and become generalized. It is by no means always a disease of advanced age or senility. He thinks it can be recognized more frequently in young adults if the condition of smaller vessels is most closely studied. There are also possible chemical changes which are important factors in its etiology; hereditary predisposition is also to be considered. He discusses the symptoms and the well-known types, renal, cerebral and cardiac, and mentions two others which he thinks have not yet been recognized. One is a spinal type which may be considered as possessing distinctive features. It occurs usually in the more or less senile states with symptoms more or less simulating tabes and not infrequently diagnosed as such. The second type to

which he wishes to call attention is the gastrointestinal. It is very probable to his mind that there is a set of gastric, intestinal and cirrhotic symptoms in arteriosclerosis, all of them depending on indurative and atrophic conditions of stomach, intestine, pancreas and liver which are the direct consequence of direct arteriosclerotic indurations. He thinks that perhaps the mild glycosuria of old arteriosclerotics may, at least in part, be due to this arteriosclerotic fibrosis of the pancreas. As to the therapeutics, he briefly urges the importance of recognition of the underlying conditions, such as the poisons of syphilis, alcohol, or other toxic action, and he has also urged, beside the use of special drugs that may be employed, the systematic use of the iodids. Prophylaxis is important, but our knowledge of physiologic chemistry and of the chemistry of arteriosclerosis in particular is too indefinite to enable us to lay down an absolute specific dietary. We should follow the general rules of diet and hygiene as borne out by experience and common sense.

12. **Nephrectomy.**—Wiener enumerates the conditions justifying nephrectomy and remarks in regard to the details of the examination and its dangers, especially those of infecting the healthy ureter and through it the healthy kidney. He divides the indications into three classes according to the age of the patient. 1. In infancy, the indication falls into two groups, congenital malformation and new growths. The former is usually an obstruction producing hydronephrosis. The tumors are usually sarcomatous. The indications for nephrectomy during adolescence are in the majority of cases, pyelonephritis, or a septic nephritic of hematogenous origin following in the wake of one of the acute infectious diseases. A perfectly healthy kidney may be thus involved. Cases are reported of operation in both cases. In adult life the indications are: 1. Hydronephrosis; 2, pyelonephritis and pyonephrosis; 3, tuberculosis, and 4, malignant growths. "The indications for nephrectomy for hydronephrosis may be summed up briefly as follows: (a) Sacs with obliterated ureters; (b) sacs with little or no kidney tissue remaining; (c) repeated failure of palliative operations, i. e. nephropexy, nephrotomy, plastic operations, extraction of stone. Only rarely in the adult will it be necessary to remove a kidney for hydronephrosis." Pyelonephritis and pyonephrosis. The surgical treatment may be summed up in two words, nephrotomy and nephrectomy. It is difficult to say which is the better primary operation. When the presence of many pus pockets renders the nephrotomy operation too tedious and dangerous, a primary nephrectomy is indicated. But on the other hand, by doing a primary nephrotomy, we give the system time to get accustomed to the use of only one kidney and have the opportunity of judging the functioning capacity of the opposite kidney before attempting to do a nephrectomy. Practically, we do not find such a marked disturbance in the urinary excretion as we do in cases of primary removal of a kidney. The remote results of a nephrotomy may be bad in conducing to the development of sepsis; or a renal fistula may remain. A case is reported. In kidney tuberculosis hematuria is often the earliest symptom, usually unilateral, is commonest in women and may remain latent for many months. The earlier the diagnosis of renal tuberculosis is made the less likely is the bladder to be affected. The symptoms to which the disease may give rise have been summed up by Morris as lumbar pain, polyuria, pyuria with acid urine, hematuria with acid urine, frequent nocturnal as well as diurnal micturition, tubercle bacilli in the urine and the general symptoms of tuberculosis. The differential diagnosis of renal calculi is often very difficult in the early stages. The malignant growths are usually found after the forty-eighth year, which is in contrast with tuberculosis which is most frequent between the twentieth and fortieth year. The new growth is usually a sarcoma or carcinoma. "The characteristic points about renal tumors are: (a) Large intestine is anterior to the tumor. On the right side the colon is usually anterior and to the inner side of the tumor. On the left side the colon is anterior and to the outer side. This distinguishes a renal tumor from one of splenic or hepatic origin. (b) Renal tumors grow forward, while abscesses generally point backward. (c)

Renal tumors do not descend as much on deep inspiration as do tumors of the spleen or liver. The three cardinal symptoms are hematuria, tumor and pain. The question as to whether a tumor in a given case is operable or not, is of great importance. Much will depend on the length of duration of the symptoms; the mobility of the tumor; the presence of edema in the loin, or in the leg on the affected side; the presence of enlarged glands, which can be felt within the abdomen, or along the brim of the pelvis. A careful examination of all the organs in the body (especially the lower urinary tract) should be made for signs of secondary new growths. The improvement in the operative results following nephrectomy for new growths has gone hand in hand with the improvement in other branches of kidney surgery. The mortality has fallen from 60 per cent. of all cases operated on prior to 1890 to 20 per cent. in 1899." The rarer conditions indicating nephrectomy are not discussed. In conclusion the author calls attention to the importance of early diagnosis as an essential for the most successful surgery.

**13. Sympathetectomy in Glaucoma.**—The following is the summary of the study of the literature by Marple in regard to this operation. "1. That the operation of extirpation of the sympathetic ganglion is a safe procedure in the hands of a skilful surgeon. 2. That (as Ziehl says), while the material is not yet sufficient to reach a positive conclusion as to the permanence of its effect, it is nevertheless established that some of the glaucomatous cases have been improved for some months by resection; in others the condition apparently remains stationary. The results have varied, and one can not yet be sure in what cases it can be advantageously employed. It at least, apparently, does no harm. A considerable number of favorable results have been reported in chronic irritation or inflammatory glaucoma, as well as in simple glaucoma, in which oftentimes pain is abolished. 3. It does not replace iridectomy, but may possibly supplement the latter, in case this is refused or has already resulted disastrously in the other eye, or is contraindicated, as in hemorrhagic glaucoma, dacryocystitis, etc. 4. Until our cases are observed more carefully and for a longer period of time, it will be impossible to arrive at positive conclusions as to the indications for the operation, or as to its permanent results."

**14. Aortic Stenosis.**—Anders reports a case in which death occurred and discusses the diagnosis and pathology of the condition. He thinks the frequency of the disease has probably been overestimated by the profession. The number of proven cases is small because of the rarity of the occurrence of all the characteristic signs. Conversely their association in the same case enables us to infer safely the existence of the lesion. These signs are: "1, a small, slow and somewhat tense pulse; 2, a systolic basic thrill; 3, an enlargement of the left chamber; 4, a harsh and musical systolic murmur over the aortic area, and a feeble aortic second sound." Certain special features are noted in his cases, viz., the gradual increased intensity of the second sound and the loud and long murmur indicating the vigor of the ventricular systole which supports the generally accepted view that the sonorous vibrations are generated by the eddies resulting from the passage of the blood through a small orifice into a larger channel, as was the case here. The dangers of aortic stenosis are not definitely decided. That there is some risk of sudden death is, the author thinks, unquestioned, even where the symptoms are of a mild character, and he reports cases from the literature where this occurred. It is highly probable that if pure cases only were considered it would prove not to be an uncommon mode of termination in this exceptional lesion.

**15. Diagnosis of Early Pregnancy.**—The points here believed to give valuable signs in the determination of pregnancy are the changes in the cervix which are of some value after the end of the second month, the differential density of the isthmus, the more pronounced softening of the center than of the lateral sections of the segment which is generally well marked by the fifth or sixth week, and is not inferior in value to Hegar's sign. When clearly defined Hegar's sign, that is, extreme compressibility of the isthmus, may be regarded as absolutely diagnostic, as the symptom is rarely counterfeited by any other

pathologic condition. Its practical value, he thinks, however, is less than that of the shape and consistence of the corpus because not so readily appreciable. The impregnated ovum lodges most frequently at the point of one cornu and the uterus is thus rendered unsymmetrical. Whether the ovum is contained in the denser or softer segment is a matter of dispute, but there is a difference in the size and tendency of the two halves a few days after the first skipped period. The marked swelling and lateral extension is a point to which it is especially desired to call attention, as it is the most easily available of the signs obtainable in the early months by bi-manual examination. In no other condition than pregnancy is softening so marked, and when pronounced it may safely be taken as proof of normal gestation. It is only after the fifth or sixth week that it is well developed and it disappears again toward the end of the third month owing to the distension of the uterus by the growth of the ovum. These conditions, however, disappear during uterine contraction and repeated examination may be necessary. The complicating presence of myomatous growths and the difficulty thus produced are mentioned and here Hegar's sign and diminished resistance of the median section of the isthmus may serve to differentiate the gravid from the myomatous uterus.

**16. Diseases of the Biliary Passages.**—Brill's article discusses the diagnosis of gallstone diseases in detail, but lack of space forbids a full abstract.

**18. Surgery of Gallstones.**—Much missionary work is necessary in Blake's opinion to secure an earlier diagnosis in the case of cholecystitis and he briefly reports a number of cases which show the lack of this and the danger of allowing the case to go too far before surgical interference. The status of gallstone surgery to-day resembles in many ways that of appendicitis of ten years ago; there is the same delay in diagnosis and the same hesitancy as regards the treatment. With reform in this regard, we will have the confidence in the surgical treatment of gallstones that we now have in that of appendicitis. More interval operations will be done. The question of cholecystectomy or cholecystotomy is discussed. There are several conditions, he says, in which cholecystectomy is the operation of choice. These are: "1, gangrene of the gall-bladder and suppurative inflammations endangering its vitality; 2, neoplasms of the gall-bladder; 3, injuries of the gall-bladder, and 4, permanent obstruction of the cystic duct. In the following conditions it is not so imperatively indicated: (a) contracted gall-bladder which can not be attached to the parietal peritoneum for drainage, and (b) calculi impacted in the cystic duct which can not be removed except by incising the duct. Cholecystectomy should not be performed in cases in which drainage is indicated, namely, 1, when there is uncertainty as to the patency of the common duct; 2, suppurative cholecystitis without sloughing; 3, cholangitis; 4, when the duct is sutured after choledochotomy and the gall-bladder can be easily and safely drained; 5, it should not be attempted in cases in which prolongation of the operation would lessen the patient's chances, as when jaundice and bleeding are present or there is impairment of vitality by disease, age or condition." As compared with cholecystectomy, cholecystotomy offers the following advantages: 1, a radical cure of the cholecystitis; 2, the avoidance of biliary fistula; 3, a perfectly clean operation with no soiling by infected bile; 4, the avoidance of adhesions. The greater mortality of the operation, he thinks, is due to the serious condition with which it has usually been associated. The only question in his mind is as to whether the gall-bladder serves any necessary principles of economy, and if not, why should we hesitate to remove it?

**19. The Patrol Ambulance.**—Donoghue describes the models of patrol ambulance in Boston and the development of the service, calling attention to the fact that similar methods are practicable in smaller towns large enough to support a hospital.

**20. The Drug Manufacturer.**—The essentials of a sound therapeutic method are given by Loomis as follows: "1, keeping in mind the tendency of self-limitation of pathologic processes and the possibility of cure as a result of natural forces, never

prescribe a remedy that will interfere with, or upset the conservative efforts of, the organism; 2, keep the problem of treatment as simple as possible by the exhibition of few remedies, well selected; 3, bear in mind the possibility of aggravating existing pathologic conditions and introducing new ones, by injudicious or too heroic methods of treatment; 4, remember that the benefit to be expected from remedies is generally offset or neutralized when a large number of remedies are exhibited at the same time; 5, try to remove the cause—this presupposes a careful study of the case, rather than a hasty prescription for this, that or the other symptom; 6, do not forget that most medicines are two-edged swords—if a medicine does no good it is likely to do harm; 7, prescribe for conditions, not diseases; 8, when necessary, hit hard, but not too often; 9, watch constantly for symptoms that may be the result of remedies prescribed for the relief of other symptoms." While more might be included, this is comprehensive enough to show the vicious tendencies that exist at the present time in therapeutics. The drug manufacture, he says, has almost passed the danger point and since its methods are purely commercial, physicians are being misled and mis-educated by it. Therapeutics of to-day are not based on the intelligent mental processes as was the case when the prescribing druggist had more of the business.

24.—This article appeared in *THE JOURNAL* of May 10, p. 1215.

25. **Disorders of the Knee.**—Gibney reviews some of the more common knee disorders, calling attention to the difference in the etiologic point of view between the diseases of adults and infants. In the latter tuberculosis is an all-important factor. In the former trauma is the most important. He insists on the importance of thorough examination, attention to the gait, and the inflammatory extension through slight injury on the functional action of the joint. He mentions in this connection a treatment which he has found very efficient in pure uncomplicated synovitis. "A strip of adhesive plaster, about an inch in width and long enough to reach two-thirds of the way about the limb, is applied about the beginning of the insertion of the ligamentum patellæ, running obliquely. A second strap crosses this; the third overlaps the first half way; the fourth the second, and so on until the upper border of the synovial sac is reached. No attempt is made fully to extend the limb, and it is left in the slightly flexed position in which it is found. Immediately following this is a roller bandage, used to make the plaster adhere more closely. If there is much pain and other evidence of active inflammation, nothing is better for the next few hours than an ice-bag. Some surgeons who are enamored of this treatment insist on the patient using the limb at once, on the theory that the action of the quadriceps femoris tendon will assist in disposing of the fluid. While this is a tribute to the adhesive plaster method, I can not help but feel that the knee joint is too important for any such experimentation, and, unless a necessity arises for the use of the limb, I prefer to have it used with caution for the next few days. At this time the parts will have shrunken a good deal, and the strapping may be reapplied." Where synovitis is late in developing and depends upon the gradual extension from a localized periostitis or from a detached fringe of the semilunar cartilage or from a subpatellar bursitis, the strapping is merely a factor in the management or an adjuvant, and here immobilization is to be considered and a posterior splint. A plaster-of-paris bandage and crutches are often necessary. Traumatic arthritis is often difficult of diagnosis. A case is reported to illustrate this fact. The physical signs of tuberculous knee are usually pronounced enough, but there are cases, especially where there is a family history of tuberculosis, that are puzzling. As regards rheumatoid affections, he says the rheumatic joints that are complicated by peri-arthritis involving the soft parts are all, in his judgment, amenable to relief, while those that are complicated by bony deposits, as in arthritis deformans, are very difficult of management. The line of demarcation between this latter disease and rheumatism he thinks is not always well drawn and time may be taken to determine the differential diagnosis. Acute arthritis developed from exposure to cold is closely allied to rheumatism. Mention is

made in conclusion of the surgical treatment of gonorrheal rheumatism, but he does not discuss a number of disorders, such as neurosis bursitis, subluxation of the patella, etc., which are omitted for want of space.

26. **The Kidney Complications of Typhoid Fever.**—The complications enumerated by Talley include, 1, albuminuria occurring in a large percentage of cases, usually disappearing early, but sometimes persistent; 2, nephritis, which is comparatively rare, may occur at any stage and is usually of bad prognostic significance; 3, hemorrhagic nephritis, which is not strongly defined from the former type, including under this head the notice of renal typhoid of Amat which the author doubts as a distinct entity; 4, suppurative nephritis; 5, pre-existing chronic nephritis, and 6, hematuria. These are also discussed and a couple of cases are reported, one of acute nephritis co-existent with typhoid and the other of probably old nephritis occurring in a typhoid patient. A tabulated statement is taken from the literature showing the frequency of these complications.

27. **The Justus Test.**—From the examination of a number of cases and a review of some of the authorities, Tucker concludes that the Justus test has no practical value in the differential diagnosis of venereal ulcers as the reaction occurs in an almost equal degree of frequency in the nonsyphilitic conditions with which syphilis may occasionally be confused.

28. **The Justus Test.**—This article by Huger on the same subject as the preceding, gives the result of examination in several cases, and he remarks: "The figures speak for themselves and need very little comment. The number of cases which I report is very few, but there are enough negative results in the group of chancres to show that the test is wholly unreliable, and, moreover, the one positive result among the chancroids detracts even more, because the failure to put a syphilitic on mercurial treatment will soon be proven a mistake, but to condemn a nonsyphilitic to years of, to say the least, unpleasant treatment, and a life-long belief that he has had and perhaps still has, the disease, is unpardonable."

29. **Inherited Tuberculosis.**—Fackler's paper is an interesting study of heredity in tuberculosis and gives statistics that certainly support the importance of inheritance in this disease. Hospital statistics show a much smaller percentage than do those of private practice which he holds to be due to the difficulty of getting good histories, and the deficient intelligence and education of the patients in many cases. He believes that we are justified in assuming that the actual degree of hereditary influence is in excess of that determined by the ordinary statistics. It is claimed by some that at least 50 per cent. of children with tubercular ancestry ultimately become tuberculous unless they succumb to some intercurrent malady. We should give special attention to the prophylaxis, proper education and training of these cases to protect them in the future, if possible. The predisposed individual should have our special care and children should be taught how to live, to love fresh air, to use respiratory and physical exercises and all other means to enrich their bodily vigor. We should also educate the laity as to the importance of heredity and the need of special care in inherited tubercular diathesis.

30. **Pneumonia.**—Nippert reports cases and discusses the diagnosis, symptoms and treatment of pneumonia and offers in conclusion as a summary that repeated and careful physical examination in any case of ill-defined infection is imperative and should not be neglected whenever the complication of pneumonia is possible. The treatment should be dietetic, hygienic and sustaining and drugs should not be administered as routine, but with a positive end in view, and in dose sufficient to obtain the desired result, such as stimulation of the heart's action and prevention of pulmonary congestion and asphyxia. The use of normal salt solution and of oxygen are a life-saving addition to therapeutics, but the control of the disease by serum of immunized animals is yet in the experimental stage.

39.—See abstract in *THE JOURNAL* of March 12, p. 781.

40. *Ibid.*

41.—*Ibid.*

**42. Chlorosis.**—Suker reviews the relations of chlorosis and concludes his summing up of the subject as follows: "1. Optic atrophy, papilloretinitis, and pseudo-albuminuric spots can and do have a chlorosis as their causative factor. 2. Double optic atrophy associated with chlorosis may simulate brain tumor to a marked degree. 3. Headaches due to a refractive error and asthenopia are of a severer type and are often aggravated by the chlorosis. 4. Arterial pulsation in the retina is indicative of the severity of the disease, as is also the venous pulse. 5. The fundus lesions in chlorosis are the result of an autotoxemia. 6. The prognosis in nearly every case is favorable, considering the severity of the hemic lesion, excepting in optic atrophy. 7. The foci of fatty degeneration in the retina deserve special attention, so as not to be mistaken for albuminuric spots."

46.—See abstract in *THE JOURNAL* of January 11, p. 125.

47.—*Ibid.*

**48. Localization of Mental Faculties.**—From a study of the authorities and cases, some of which are reported, Phelps maintains that the following three propositions are justified: "1. The more absolutely the lesion is limited to the left prefrontal lobe the more positive and distinctive are the symptoms of mental default. 2. The integrity of the mental faculties remains unimpaired in right frontal lesion, though it involves the destruction of the entire lobe, or even extends to the entire hemisphere. 3. The exceptional instances in which seemingly opposite conditions exist are always reconcilable, on more careful examination, with the assertion of an exclusive control of the mental faculties residing in the prefrontal region of the left side. If, then, the same nature and degree of proof which is deemed sufficient for the localization of other cerebral functions may be accepted in case of the mental faculties, their center of control has been established."

**49. Kernig's Sign.**—Sailer reports two cases in which Kernig's sign appeared to be associated with focal encephalitis and was localized on the opposite side of the body. It was also associated in one instance with spastic paralysis and there was also a chronic spasm of the flexor muscles of the arm which, however, did not resemble the Kernig's sign in its mechanism. The most reasonable explanation of the symptom, he thinks, is to ascribe it to an irritable lesion of the pyramidal tract that diminishes but does not destroy its functional activity.

**50. Kernig's Sign.**—Five cases out of 100 examined by Shields, all non-meningitic, showed Kernig's sign; 3 of them were unilateral and 2 bilateral and ceased after recovery, in one case of hemiplegia and one of typhoid fever. The sign persisted in the remaining cases, 2 of right-sided hemiplegia and one of typhoid fever which is unilateral and persistent, though the case of typhoid has not yet recovered and it may disappear.

**51. The Kernig's Sign.**—Clark reports three cases of meningitis, two tubercular, in which this sign was absent and forms the opinion that it is unreliable in tuberculous meningitis.

**52. Lateral Sinus Thrombosis.**—Dench has operated on 22 cases of sinus thrombosis with 2 deaths, one from septic pneumonia and the other from nephritis apparently induced by the anesthetic. In 4 of the cases only was it found necessary to ligate the internal jugular vein and all of these cases recovered. He believes that prompt surgical interference of the most radical kind is the only safe course, and he details his method and reports cases. He thinks it wise in all doubtful cases to resect the internal jugular vein to eliminate the possibility of infection, though he does not prescribe this in all cases. Where the patient has been under observation for a few days and we have a fairly complete temporary record of 24 to 48 hours showing no marked evidence of systemic infection, the surgeon may rely upon simply clearing out the clot in the sinus if it is to be found. This same method should be followed in cases which first come under observation at the time of operation. The sinus can be fairly well cleared out by the curette. On the other hand, in those cases which are first seen at the time of operation and in which the sinus can not be thoroughly cleared and in which also the surgeon is confident that a certain amount of infected material is left

in the venous canal, he thinks immediate excision of the jugular vein is demanded. The operation is not a serious one, takes little time, does not endanger the patient by prolonged anesthesia and prevents further systemic infection. The temperature is the only real guide.

**54. Infantile Paralysis.**—Gossage reports cases illustrating the types and reviews the literature as regards the theories of infantile paralysis. It is impossible, he thinks, to come to any definite conclusion as to the nature of the disease. Clinical records are strongly in favor of at least two and it may be three or four definite diseases being included under the term anterior poliomyelitis, namely, "1, that class where the paralysis comes on suddenly without previous ill-health; 2, that class where the onset of the paralysis is preceded by general symptoms, such as fever, vomiting, pain in the back, etc.; 3, the epidemic class, and 4, the adult class. The three latter may possibly be the same disease which may sometimes occur sporadically, and at other times in the form of an epidemic." The one definite fact obtainable from the post-mortem examination of all patients that have suffered from the disease is that there are signs of local inflammation in the ventral horn. The disease, he thinks, is probably caused by some micro-organism not yet isolated. It is possible that there may be two or more specific organisms.

**56. Hepatic Lesions in Infancy.**—From an examination of 270 consecutive autopsies of infants, Wollstein finds that fatty liver occurred most often with suppurative inflammation and, next in frequency, with tuberculosis, pneumonia and the intestinal diseases. Fatty liver is never found in uncomplicated marasmus and is inconstant both in syphilis and rachitis, all cases of which were complicated. In one case there was a hypertrophic cirrhosis and in another there was a similar condition due to obstruction of the bile-ducts in a child of three months which was reported in the *Archives of Pediatrics*, for March.

**57. The Sacrococcygeal Dimple.**—Markoe and Schley's article is mainly the discussion of the literature with description of the conditions. They find transitions from the simple congenital dermoid cyst to the larger and more complex dermoids and to various other conditions, teratoma, etc., and even of true fetal inclusion. Their importance depends on their liability to irritative influences and traumatism. The only real successful treatment is complete and radical extirpation of the whole tract down to the periosteum of the bone as soon as practicable.

**59. Chronic Interstitial Pancreatitis.**—The following are Opie's conclusions: "1. Chronic interstitial pancreatitis is slightly more frequent in males than in females. Two-thirds of the total number of cases occur between the ages of 40 and 60. 2. The most frequent cause of chronic pancreatitis is obstruction of the duct of Wirsung, due to pancreatic calculi; to biliary calculi in the terminal part of the common bile-duct, or to carcinoma invading the head or body of the gland. Duct obstruction may be followed by the invasion of bacteria, which take part in the production of the resulting lesion. 3. Ascending infection of the unobstructed duct of Wirsung may follow an acute lesion of the duodenum or of the bile passages and may cause chronic inflammation. In cases which have given a history of long, persistent vomiting, chronic diffuse pancreatitis may be found at autopsy, and is probably the result of an ascending infection of the gland. 4. General or local tuberculosis is occasionally accompanied by chronic diffuse pancreatitis, affecting chiefly the interstitial tissue of the gland. 5. Chronic interstitial pancreatitis is not infrequently dependent upon the same etiologic factors, notably alcohol, which produce cirrhosis of the liver, and in about one-fourth of the cases the two lesions are associated. 6. Following duct obstruction and ascending infection the lesion affects principally the interlobular tissue, only secondarily invading the lobular tissue and sparing the islands of Langerhans. Diabetes results only when the lesion is far advanced. 7. Accompanying the so-called atrophic or Laennec's cirrhosis of the liver, the pancreas is at times the seat of diffuse chronic inflammation, characterized by diffuse proliferation of the interacinar tissue, which invades the islands of Langerhans. A similar lesion accompanies hyalin degeneration of the islands of Langerhans

and the condition known as hemochromatosis. 8. Interacinar pancreatitis is usually accompanied by diabetes mellitus. When diabetes is absent the lesion is of such slight intensity that the islands of Langerhans are little implicated."

65.—This has appeared elsewhere. See THE JOURNAL, May 17, American abstracts 29 and 45, also this issue No. 70.

67. **X-Ray in Acne and Sycosis.**—Pusey reports a number of cases of acne treated by the x-ray with great success and says there is no other affection which proves so tractable, and the results have been produced quicker and with less effect on the tissues than we should imagine was possible. He thinks in such cases the light should be from fairly-soft tubes and only just enough to show a faint green color in the tube. Of course, in treating such cosmetic disorders the danger of producing bad results from the rays must be considered and he warns against using anything but the very weakest light in these cases. He also reports a case of sycosis which did not respond to other treatment, though of moderate severity, therefore the patient was put under the x-ray exposure for some time. There was hardly any improvement for over eight weeks and slight dermatitis was produced. The treatment was continued, however, until the dermatitis became acute and alopecia resulted. Rapid improvement in the sycosis occurred in about three months after the beginning of treatment, all evidences of the disease had shortly disappeared and he has had no trouble since.

70.—See No. 65.

72. **Asthma.**—Jack thinks the origin of asthma is to be sought in the state of the blood and he recognizes an asthmatic lymphocytosis, due to a toxemic form of leucocytosis, and an asthmatic anemiasis. He holds that the nerves take no part in any of the phenomena of asthma other than the performance of a physiologic duty and supports his view by the facts of blood examinations, etc.

83. **Regenticides.**—This paper of Spitzka's, which is begun in this issue, takes issue with Talbot and Regis as regards the association of regenticide with insanity and, as its title indicates, considers the subject in a statistical manner. He goes over the history of various noted cases, such as the Orsini conspiracy and other historical conspiracies, and he claims that, with the insane taint, the lack of accomplices is rather exceptional than the rule.

86. **Yellow Fever.**—Ross, who is a surgeon in the U. S. Navy, has made experiments in the Las Animas Hospital, Havana, similar to those performed at Quemados, as to the transmission of yellow fever by fomites and calls attention to the following facts in connection with the experiments. They were conducted in the City of Havana itself where yellow fever has run riot for 139 years and in buildings similar in construction and material to those occupied by the people of the poorer classes—damp, poorly-lighted, badly ventilated, floors on the ground, and they also were conducted in the season when the scourge is usually at its worst. The clothing, etc., was taken from thoroughly diagnosed cases and was used by 8 patients all non-immunes, and every possibility of contagion from this source was insured without any results, other sources, of course, being excluded, and he believes that we should adopt the conclusion of the yellow fever commission, as confirmed by these experiments, that yellow fever is not conveyed by fomites and hence disinfecting of articles, clothing, bedding and merchandise supposedly contaminated is unnecessary.

93. **Pre-Historic Tuberculosis in America.**—Among some other interesting facts in regard to Indian medicine and recent Canadian medical folklore, Addison reports that he examined an ossuary near Big Bay Point, in the county of Simcoe, Ontario, in which he found some trephined crania and what was still more of interest, in several skeletons the evidence of Pott's disease. The bones were those of natives of the Huron nation and had undoubtedly been underground over two centuries. He thinks the evidence shows there was tuberculosis among them, not only before the European invasion, but that it was far from uncommon, and that these cases occurred in a nation which was not nomadic, but had permanent places of abode, there being thus a tendency to the accumulation of infective material.

100. **Adrenalin.**—Howard experimented with adrenalin in the treatment of gonorrhea, employing it in solution of 1 to 4000, first flushing out the urethra by urination and then administering the solution, following this with a further washing out with an aqueous one-per-cent. solution of protargol. This has had to be repeated several times in some cases, but a quick cure was obtained in nearly all. In every case the discharge was promptly and markedly lessened. The recovery was with a promptness very unusual in his experience and without complications. He has not felt justified in using the adrenalin alone for he is not satisfied that it has any germicidal value. He has also treated a case of stricture with good results.

101. **Castor Oil in Typhoid.**—The treatment here suggested by Bass, which he has employed in a number of cases, is the giving of quinin and calomel for three or four days to eliminate the possible malaria and after this a dose of castor oil every morning. In no case was high temperature prolonged beyond twenty-five days, except in one where it returned after falling below normal and was quickly reduced by the same treatment. In no case did hemorrhage occur; delirium also subsided, but after every case there was a poor recollection of the events that occurred during the illness. He does not claim a curative effect in typhoid, but thinks that the oil washes and clears out the poisonous accumulations in the intestines which cause an elevation of temperature. The dose should be large enough to act in four to six hours, varying from two teaspoonfuls to two tablespoonfuls according to the condition of the bowels. The oil can be given in sweet milk in a hot cup and then it will be taken with little difficulty.

102.—This has appeared elsewhere. See THE JOURNAL, April 26, p. 1106, No. 13, and May 3, p. 1179, No. 62.

105. **Surgery as a Last Resort.**—Lawrence thinks the tendency to delay in resorting to surgical operations is largely due to prejudice and overconfidence in the recuperative powers of nature and drug action, to failure to recognize the surgical nature of the disease, to the too prevalent use of the term surgery as a synonym for operating, and lastly, to financial considerations. He maintains that some conditions are surgical and should be surgically treated from the start and the question of operation should be determined by the surgeon and not by the practitioner. Last-resort operations should seldom receive surgical sanction. To the lay mind the surgical operation is a surgical operation regardless of the skill of the operator or coöperative power of the patient. The harm done to the living who may be influenced in cases of similar character should always be considered before we stigmatize surgery by operating upon moribund patients. Only rarely should surgical operations be advised or sanctioned where there is not a reasonable hope of the prolongation of useful life or cure in case the patient survives the immediate effects of the operation. No case should be considered too desperate to attempt in which we know, if the patient survives the operation, cure will result.

1. **Skin Eruptions.**—The common recognition of the relation of skin eruptions to general diseases is first mentioned. Galloway then remarks that he can only notice a few cutaneous signs of internal disorder. First, in renal disease, there are many eruptions directly connected with the treatment; measures for producing elimination through the skin producing various forms of sweat rashes, but there is one form seen from time to time, a nephritis in which the skin manifestations are of a different nature and in which the prognosis becomes more grave with the severity of the eruption. The form he refers to is a vasomotor paralysis apparently of the cutaneous capillaries followed by effusion of serum or even of blood into the upper layers of the cutis. This reproduces the various forms of erythema multiforme with exudation, and usually indicates serious renal and blood changes. If well-developed it is a bad prognostic sign. It usually ends in desquamation of epidermis to a greater or less extent and in the severest types it resembles a form of acute exfoliative dermatitis seriously aggravating the later stages of Bright's disease when it occurs. The subject of skin eruptions during diabetes is too extensive to be covered, but one or two features are noticed. It is probable that it is the general diseased condition predisposing to bacterial infection that produces these disorders. There are probably very few eruptions peculiar to diabetes. Special care should be taken in guarding the patient against infection, so as to avoid the very troublesome and even fatal boils and carbuncles which may result. Two interesting conditions, however, to which the diabetic patient is prone, are specially mentioned; one is the circinate scaly eruption generally known as seborrheic dermatitis, which occurs frequently in diabetic or gouty forms of glycosuria. The patients are usually of middle age and frequently too stout. The eruption is sudden in its appearance and it may cause troublesome pruritus and lead to development of eczematous inflammation. The first point in the treatment is to recognize the dietetic element and regulate the diet accordingly, observing the condition of the urine. For local treatment, prompt medicated baths are usually of value, especially weak sulphur baths followed by a lotion containing prepared calamin 20 gr., zinc oxid 15 gr., lime water 1½ dram, glycerin ½ dram, rose water 1 oz.; to this lotion from .5 per cent. to 1 per cent. of the liquefied carbolic acid may be added if there is much pruritus. Special dermatitis and pruritus of the genitalia are also mentioned. It is possible that the starting-point of this irritation is from the diabetic urine. The acid reaction of fermented secretion allows the growth of numerous micro-organisms and aggravates the conditions and finally the disease becomes permanent and incurable. Ulcers resembling chaneroids may appear. The treatment of the condition is often satisfactory. It should consist in local washes with mild antiseptic and astringent lotions applied warm, oxid of zinc ointment, warm baths, etc. In antipruritic treatment it should be remembered that the phenazone group of drugs and chloral hydrate are of occasional service. Opium is of little value, but the diet should receive attention to regulate the general condition. Finally, Galloway mentions a class of disorders seen in what he calls persons with

low tension circulation, consisting in a sort of vasomotor paralysis of the capillary system and with this a tendency to the aggravation of conditions after infections when they occur. There may be no organic disease of the heart detectable, but as a rule, the pulse rate is probably less frequent than normal. In some severe cases tachycardia very exceptionally occurs. There is one point of considerable importance in connection with this type of circulatory skin disease. Its resemblance to certain so-called tuberculids of the skin, such as necrosis, with scar with a minimum amount of ulceration when the infiltration is small as from the occurrence of passive localized congestion or the occurrence of a general amount of sometimes great cellular infiltration of the cutis. As an example of the first type of these we may take what is called necrosing dermatitis of the extremities and acne scrofulosorum, and of the latter the condition known as erythema induratum scrofulosorum or Bazin's disease. The resemblance of this diabetic form of skin disorder with these tuberculids may lead to serious mistakes in diagnosis. As regards treatment, the author dwells on the importance of general hygienic and dietetic measures, keeping the patients in the best condition of nutrition, the skin in the best order by scrupulous cleanliness, by frequent warm baths, careful drying of the skin, and the use of warm and well-fitting clothing. Patients who are seriously affected suffer much inconvenience, become very much depressed and require tonic treatment. In the mild cases the use of cardiac and nerve tonics, especially digitalis and strophanthus and strychnin, either in combination or alternately, produce very gratifying results.

2. **Chloroma.**—Dunlop reports a case which he thinks is the first that has been diagnosed *intra vitam*, and discusses the pathology of the condition. He thinks these tumors generally belong to the type of lymphosarcoma and the color, he thinks, is probably due to some chemical product allied to lipochrome, hitherto undiscovered, which on exposure to light becomes oxidized and in the process of oxidization loses its color. The tumors originate from the periosteum of the head and face and those met elsewhere are secondary forms. They invade the cavities of the skull, the marrow of the bones, and the internal organs having a very rapid generalization and multiple metastases in the body. Their consistence varies considerably. Microscopically they are found to consist of large round or oval-shaped cells with numerous nuclei, and occasionally nucleoli, imbedded either in an intercellular amorphous material of a very clear and transparent character or in a delicate network, or in other cases the tumor is interspersed by coarse bundles of connective tissue forming lines of demarcation. In the midst of this network granules with highly refractive properties are found lying in and between the cells. It is chiefly a disease of children and adolescents, occurring more frequently in boys than in girls. Its close resemblance to leukemia is pointed out by Recklinghausen and Dock. The exophthalmos is one of the most usual things in chloroma and a similar condition has been described in several cases of leukemia. In both anemia is present with petechiæ, extravasation under the skin, epistaxis, and conjunctival and retinal hemorrhages. There is a very striking lymphocytosis and a remarkable diminution in leucocytes. Dock is of the opinion that it stands between ordinary cases of leukemia and those described by Ebstein as acute leukemia and that there is strong evidence in favor of new growths found in chloroma being the source of lymphocytes as there is of the thymus, bone marrow and spleen being their source in leukemia. The termination is invariably fatal from exhaustion, the average duration not over five or six months.

7. **Goiter.**—Berry describes the different forms of goiter, first the parenchymatous, the common type observed in young people, tending as it grows old to become fibrosed. The second class, encapsulated form often unilateral and one of the most common types seen in Switzerland and Derbyshire, and may be compared to the common adenomas of the breast or to the encapsulated fibroids of the uterus. A common secondary change in these cases is fibrosis, the tumor being converted into a mass of fibroid tissue. Generally it springs from the lower part of one lateral lobe and may cause serious embarrassment by

pressure on the trachea. Sometimes it may be complicated with the parenchymatous form and it may be multiple. When other means of diagnosis fail between these two types it would be well to administer iodine or thyroid extract for a time. If the goiter is of the parenchymatous type it will probably disappear or lessen in size with this treatment, while if it is an encapsulated tumor it will be unaffected. It is a good idea, however, to use such medical treatment before attempting operation in any case as the parenchymatous goiter existing around the tumor will be decreased and the tumor lessened and its enucleation facilitated. The exophthalmic variety is briefly mentioned; it is of far more serious importance than an ordinary parenchymatous goiter, for which it may be mistaken. Persisting rapid pulse being present with a uniform enlargement of the thyroid should raise a strong suspicion of this disease, though these symptoms are not always absolutely pathognomonic. Malignant disease does not usually present any great difficulty in diagnosis and seldom occurs before the age of 40 and the general rule is that when in a thyroid gland of a person over 40 years of age a hard tumor exists, steadily and rapidly increasing in size and not of inflammatory nature, malignancy should be suspected. A nodular, lumpy character of tumor also is an aid to the diagnosis as well as its hardness, but there is a form of sarcoma which is quite soft, and the steady and rapid growth and nodularity are the most characteristic features. A special form of malignant disease of the thyroid which runs a much slower course is a papilliferous cystic tumor extremely suitable for operation. Another unusual form is what is called malignant adenoma. This is likely to disseminate itself generally. It includes a number of distinct forms. As regards the treatment of goiter he mentions the importance of investigating the drinking water as most cases of the parenchymatous form of the disease are probably dependent on this. Iodine and thyroid extract are the principal drugs to be used. The operative treatment of goiter is confined largely to the malignant or encapsulated forms. Enucleation is suitable only for encapsulated tumors. If the operation is performed on suitable cases it is almost devoid of danger, the safety depending on the diagnosis. In the great majority of cases of parenchymatous goiter no operation at all is desired and it should not be done for mere deformity. In only dyspnea of a serious nature has it an excuse. As regards exophthalmic goiter, Berry condemns operation absolutely. Malignant disease is seldom seen early enough to permit of any operation, and whenever it is attempted considerable difficulty should be anticipated. If it can be done in its very early stages it is not a serious proceeding, and presents little difficulty.

**8. Typhoid Fever.**—The concluding portion of the third lecture of Corfield reviews the various methods of contamination and direct contagion of which there is some evidence, and the air-borne typhoid in various ways. He notices the vitality of the germ in the soil, showing that it may live for an indefinite period under favorable conditions and the element of soil infection must be considered. In the conclusion of his paper he gives some tables showing that the rate of mortality in England, Wales and the city of London has decreased each semi-decade from 1870 to 1900.

**11. Inoculation for Typhoid.**—Crombie's article gives a tabulated statement of the result of inoculation in certain detachments of troops during the South African war. It does not seem to point to any great value of the method. He remarks, as of general interest, that a medical officer found six months after inoculation that his blood gave a well-marked agglutinin reaction, and a fortnight afterward he was in bed suffering from enteric fever, showing that the presence of agglutinin is no guarantee of the alexins. His deductions are incomplete, but he offers them as a contribution preliminary to the completion of official statistics on a large scale which he hopes will be possible after the conclusion of the war.

**14. Hematuria.**—The characteristics of idiopathic hematuria as shown by cases and summarized by Guthrie are: "1. It is hereditary, familial and congenital. 2. The hematuria may be persistent for many years but may vary in extent. In some cases it may cease for a time, but in all it is apt to recur

or to increase in paroxysmal attacks or exacerbations. For instance, in one of my cases the urine examined almost weekly for upward of two years has never failed to contain blood visible to the naked eye and give a marked reaction with ozonic ether and guaiacum. Its color varies from that of old gold tinged with red to the bright scarlet of oxyhemoglobin. In another, blood is always present but can only be detected on microscopic examination, except when exacerbations occur. At these times the urine may resemble almost pure arterial blood. It is not "smoky" in appearance, but is "red," the color being due to oxyhemoglobin, not methemoglobin. Normal red blood corpuscles and blood casts can always be found under the microscope; so that the color is not due to hemoglobinuria. The amount of blood passed during exacerbations is always far greater than is ever seen in cases of nephritis and resembles in profuseness the blood passed in the cases of renal calculus or new growth. 3. All cases are liable to paroxysmal exacerbations of hematuria which are usually accompanied by slight pyrexia, malaise, headache, vomiting, and slight pains in the back or limbs. The exacerbations are often attributed to "catching cold" and are associated with slight bronchial catarrh, or with trivial ailments, such as toothache, earache or tonsillitis. In some cases articles of diet, such as black currants, asparagus, strawberries, claret and perhaps rhubarb, have been held to produce them. But the exacerbation may occur without complications and in the absence of special causes. The duration of these exacerbations is usually several days, but seldom exceeds a week or at most a fortnight, and after the first few days the blood gradually lessens in amount. They have no law of periodicity or of frequency. They may occur at intervals of weeks, months or years, but they appear to become less frequent after the first decade is passed. They occur with extreme suddenness by day or by night and are not influenced by posture. Extremes of hot or cold seem to give rise to them. 4. Idiopathic hematuria is not associated with edema nor with ascites nor with the cardio-vascular changes following ordinary nephritis. Except at times when exacerbations occur the subjects appear to be, and are, in perfect health. They may be temporarily anemic after an exacerbation, but it is not profound or lasting. 5. The hemorrhage is not due to the presence of uric acid or oxalates. A few crystals of these substances may often be found on microscopic examination, but free gravel is never passed, neither is there any excess of uric acid in solution. The amount of urea passed is normal. 6. The specific gravity of the urine is not unduly low. It varies from 1015 to 1030. The quality of urine passed is not above or below normal. The reaction is acid or neutral. The urine is nearly always albuminous, the albumin varying from one-twentieth to one-fourth of its bulk. Sometimes it is in accordance with the amount of blood present, at others it exceeds it. Nucleo-albumin is usually passed as well. The sediment nearly always contains free normal red blood corpuscles and tubular blood casts in more or less abundance, but never hyalin casts. Finally, none of the subjects of idiopathic hematuria is a 'bleeder.' One of them recently had some adenoid vegetations removed and the hemorrhage caused was neither profuse nor prolonged. None of them suffers from Raynaud's disease or from purpura. Scarlet fever can be excluded as a cause in all cases and also calculus, new growth, congenital syphilis, renal tuberculosis, and all forms of nephritis. The kidneys are not movable, palpable, nor tender, and there is no definite nor constant local pain." A report of the cases follows. He remarks in conclusion that the explanation of this mysterious disorder is still to be discussed. The fact that the hematuria is congenital excludes all the ordinary known causes. The most reasonable supposition is that there is some inherent weakness or varicosity of the walls of the renal vessels leading to what may be called renal hemophilia, or renal epistaxis. The vasomotor system may be at fault, in which case the complaint might be grouped with cyclical or postural albuminuria, but in this case it is not postural. This class of exacerbations occur as often during the night in bed as in the daytime. The diagnosis rests on the personal and family history; on the occurrence of febrile exacerbations in which the hematuria far exceeds that of acute nephritis; on the absence of edema, dropsy and cardio-vascular changes, and

finally, on the absence of any of the well-known causes of hematuria.

**19. Plague.**—Japan seems to have successfully met plague in Formosa by inoculation with Kitasato's serum and Maxwell gives an account of the method. The operation is very simple and painless and inoculation is made compulsory by the authorities. He has attended a good many cases of plague but only came across two cases in inoculated persons, in which one was so mild that the patient was hardly laid up. In the other it was most severe, but the inoculation had only been performed once. He says, to sum up, the method is easily applied, causing a minimum of discomfort and a very large reduction has been made in the numbers attacked by plague in Tainan and a decided reduction in the number of deaths among those attacked.

**28. Bacteriology of Infections of the Bladder.**—Faltin states that the bacteriology of the bladder is very variable. The colon bacillus is found more frequently in chronic than in recent infections, and the urethra is usually the route of infection. This bacillus does not seem to be antagonistic to other flora except to certain staphylococci, but the pyocyanus displays a tendency to smother or drive out of the bladder all other microbes.

**29. Catheterization of the Ureters and Radiography.**—Tuffier first suggested the practicability of inserting a metal guide in the ureter catheter for the purpose of radiographing it. De llyès claims that he was the first to act upon this suggestion, and reported his results at a meeting of his local medical society, April 13, 1901. In his first case he was able by radiography to exclude the kidney as the source of a tumor which could be palpated in the abdomen, and also to determine the movability of the spleen. In the second case he was thus able to diagnose and locate a renal calculus. The shadow cast by the stone was so faint that it did not attract attention until the radiograph showed that the tip of the catheter was abruptly arrested at this point. Microscopic crystals also emerged through the catheter, and its application allowed the escape of a collection of pus above the calculus, followed by the subsidence of the fever. Small calculi can be made to cast a distinct shadow by exposing only a limited area to the rays, not more than 2.5 cm. at a time, thus excluding the reflected rays. The stones can be located by a radiograph of the catheter as above, and then by exposing the exact spot, they will cast a good shadow. Displacement of the kidney can also be diagnosed by this means. In one case the catheter was arrested close to the kidney. No fluids escaped and there was no evidence of retention in the pelvis. These findings indicated that the tumor palpated was really in the kidney and that the catheter was arrested by the mass of neoplasm which had replaced the true kidney tissue. In his fifth case a young pregnant woman had noted for two years a movable tumor in the right hypogastrium as large as a fist. It was held firmly by an assistant and a radiograph of the catheter in the ureter showed that it passed directly into the tumor which was thus differentiated as a movable kidney. The intestines must be thoroughly emptied before undertaking catheterization for this purpose. Ulyès administers a purgative two days before and allows only liquid food. He uses a fine silver guide 1 to 3 mm. in diameter, but suggests that all possible danger might be averted by filling the catheter with bismuth instead of using a stiff guide.

**31. Absorption by the Bladder.**—Barbaroux states that the mucus in the bladder interferes with absorption by the epithelium; any measure which removes the mucus, irrigation or instillation of a dissolvent, favors absorption. On the other hand, introduction of a substance which precipitates the mucin retards absorption. When the epithelium is altered in its structure, absorption proceeds more rapidly, but simple inflammation diminishes the absorbing power of the organ on account of the enhanced secretion of mucus. The walls of the bladder have no specific absorbing apparatus, but under certain circumstances they allow the passage of some substances, even of the urinary excreta.

**38. Mediastinal Serous Pleurisy.**—Chauffard illustrates two typical cases of pleurisy with an effusion collecting in the

mediastinum in the shape of a vertical band or prolonged at the bottom in the shape of a carpenter's square as the diaphragm becomes involved. These forms of pleurisy are rare and peculiarly insidious. They may be discovered by radiography or physical exploration or they may be masked by the "mediastinal syndrome." One of the four cases he has had occasion to observe occurred in the course of typhoid fever and the large effusion in the right mediastinum soon entailed the compression of heart and lung, but the patient recovered without evacuation of the fluid. He was able to find only eight cases previously recorded. The serosa of the mediastinum is first affected in these cases, then of the diaphragm, and finally the pleural cavity. As the latter becomes involved the inflammation of the other serosæ subsides.

**40. Oily Solution of Digitalis for Subcutaneous Injections.**—Rosenthal quotes numerous writers to the effect that in many cases the administration of digitalis by subcutaneous injection would be a great advantage over the ordinary method. The objection hitherto has been that the alcohol or chloroform, etc., in the solutions used has made the injections painful and entailed abscesses and even necrosis. He has now obviated these objections by the production of an oily solution which is stable and especially adapted for injections of this kind. It contains one-eighth of a milligram of digitalis to the cubic centimeter, and extensive tests on animals have confirmed its efficacy and absolute harmlessness. None of the patients who have been injected with it showed any tendency to inflammation or induration at the point of the injection.

**51. Lumbar Puncture After Fracture of the Skull.**—Rochard followed Tuffier's suggestion in regard to lumbar puncture as a means of diagnosing a fracture of the skull, and tried it on two patients. The escape of even a small amount of cerebrospinal fluid aroused the patients from their stupor and recovery was soon complete. Lumbar puncture has therefore direct value as a means of relieving and aiding recovery from injuries of this kind, but as even slight contusions are sufficient to induce more or less extravasation of blood, it has no diagnostic significance. Others have recently reported the relief of severe headache by this means, especially syphilitic cephalalgia.

**56. Hyperthermia.**—Petit-Vendol reviews three cases of sudden attacks of hyperthermia which have been published since 1898 and urges more detailed descriptions of such experiences. The physicians were inclined to attribute the hyperthermia to a nervous origin. The high temperature appeared suddenly in each, without affecting the general health or spirits or even the pulse, and with no explanatory signs. The physician at the first attack in one case merely supposed that his thermometer was out of order.

**57. Nervous System in Consumptives.**—Chelmonski has found symptoms of neurasthenia, hysteria or of both combined in nearly every consumptive examined. He thinks that the nervous system should be considered in the treatment of tuberculosis more than of any other chronic disease.

**58. Heredity in Odors.**—Féré describes the case of a woman who noticed the complete suppression of the odors of the cutaneous secretions at the moment of fecundation. It occurred regularly in her five pregnancies, also in her mother's three and her sister's two. The family were always able to determine the date of fecundation from the cessation of the odors, and their reappearance announced the return of the menses. The only similar occurrence which Féré has found recorded is Morren's statement that the fragrant orchids, such as the *Marillaria aromatica*, lose their perfume in half an hour after artificial application of the pollen, while the non-fecundated flowers retain their perfume for a long time.

**68. Libby's Method of Treating Otitis.**—Melzi first cleans the ear with or without hydrogen dioxid and then insufflates acetanilid according to the directions of G. Libby of Portland, Me. He is very enthusiastic in regard to the value of this method of rapid cure.

**70. Uremic Stomatitis.**—Hirtz points out that the differentiation of uremic stomatitis may often clear up the diagnosis

of the uremia. The physician should seek for the stomatitis in all cases of uremia. Treatment should be addressed to the latter, German brandy, dry cupping and possibly venesection to aid in the elimination of the toxins. The mouth should be rinsed with a solution of boric acid, permanganate or better still, hydrogen dioxide which has a marvelous action on the anaërobic microbes which swarm in these cases. As a collutorium, potassium chlorate, iodine or lemon juice will be found useful. The prognosis is grave on account of the uremia of which it is merely the expression, but a cure is possible. The stomatitis may be erythematous-pultaceous or more rarely merely ulcerative. The ulcerations may be diffuse but they have always spared the tongue, tonsils and pharynx in the cases known to date. Barié states that 900 gm. of saliva were excreted by one of his patients.

**72. Progress to be Realized in Treatment of Severe Syphilis.**—Leredde urges that the severe manifestations of syphilis should be treated by mercury alone, and that the current doses should be considerably increased. If the teeth are in good condition there is no danger of stomatitis. The physician should not wait for the appearance of the severer manifestations of syphilis to demonstrate that his doses have been inadequate, but should start at once with large doses, when the ordinary methods of treatment have proved ineffectual. Inunctions of 4 gm. of mercurial ointment are altogether insufficient for a syphilitic exhibiting symptoms of nerve involvement. Without waiting for paralysis or tabes to appear, the physician should administer in subcutaneous injection 3 to 4 cc. of the cyanid or sublimate or 6 to 8 cc. of the weaker salts, the benzoate or biniodid. These doses can even be increased if necessary. An injection twice a week of 7 to 10 cc. of calomel might be tried. These doses are calculated for a robust man. For women they should be reduced about 25 per cent. The parasymphilitic affections are generally curable if treated on these principles, but not if the ordinary methods of mercurial treatment are followed.

**73. Postoperative Alexia.**—Bard describes a case of assumed traumatic epilepsy in a man of 56 who insisted upon an operation as a last resource. His condition was not improved in any way by the intervention and total alexia supplanted the partial previously observed. Bard emphasizes anew the dangers of functional aggravation of the condition by surgical intervention on a region of the brain evidently already thrombosed and in which the circulation is already profoundly compromised.

**74. Carcinoma and Alterations of the Skin.**—Hollaender called attention two years ago—as *THE JOURNAL* mentioned at the time—to the frequency of red spots, warts and pigmented patches on the skin of persons with incipient or developed carcinoma. He considers them premonitory symptoms of an impending internal cancer. The red dots are angiomas and may be the size of a pinhead or bean, but are usually still smaller. They occur in the midst of sound skin, and project a little above it. These little formations, of course, occur frequently in healthy persons, but not with the suddenness, the constancy and in the numbers observed in case of malignant neoplasms. There is also a tendency to warts and to pigmented patches like large freckles. The latter occur usually on the covered portions of the body and are most numerous in the vicinity of the cancer, especially in case of cancer of the rectum. He ascribes the greatest diagnostic importance to this member of the triad, but considers the combination of the three a most significant and valuable sign of impending cancer, especially in the comparatively young.

**75. The Steam Saw for Resection of the Liver.**—Koslenko describes Sneguirev's instrument as a saw, hollow through the handle to the tip, with a small opening between each tooth of the saw. It is connected by a rubber tube with the steaming vessel and, as it saws, the steam penetrates directly into the cut tissues without injury to the operator or to any other part of the tissues. Tests on the livers of dogs showed that the steam saw enables the liver to be resected in any direction without the danger of hemorrhage. In case a large vessel is

severed, the steam can be applied in a large jet to the spot or turned off and the vessel ligated. There was no secondary hemorrhage after resection in this way, and the wound in the liver healed by granulation with formation of considerable connective tissue. He expresses, in conclusion, his anticipation that steam will be found as effective a hemostatic in surgery of the parenchymatous organs as it has proved in gynecology.

**78. Artificial Sterilization of Consumptive Women.**—Neumann's further experience has confirmed the efficacy and harmlessness of his method of preventing conception in phthisical women. The point of insertion of each tube in the uterus is drawn out in turn through a buttonhole in the peritoneum, and a wedge-shaped piece excised. Very little chloroform is needed. Menstruation is retained, while conception is absolutely prevented.

**81. Drainage After Symphysiotomy.**—Zweifel describes five cases in which he secured aseptic healing under the usual adverse circumstances by draining through a channel pierced through the labium on one side, below the corpus cavernosus clitoridis. The drain tube thus emerges on the outside of the labium majus, and all danger of infection from the lochia is averted. He thinks the certainty of aseptic healing guaranteed by this method of drainage will remove the principal objection to symphysiotomy.

**85. Behavior of White Corpuscles in Suppurative Processes in Female Genital Apparatus.**—Dützmänn reports that the blood count in the twelve patients examined showed invariably an increase of white corpuscles in case of suppuration. Any retention of pus sends up the number of leucocytes. In one case every sign indicated carcinoma, but the whites numbered 16,400, and the patient recovered after the suppuration indicated by this increase had been discovered and evacuated. The number of white corpuscles in some of the cases which he tabulates was 17,800, 31,300, 15,900, 18,200 and 12,100, with temperature of 36.8 to 38.6 C. In other cases the white corpuscles numbered 9600 and 9900, with temperature of 37.5, and the course of events disclosed the absence of pus and the sarcomatous nature of the tumor. He says that the sign never failed, and he proclaims that we have in the blood count a most valuable aid for the differentiation of gynecologic affections. [Küttner observed at the recent German Congress of Surgery that a complication may be suspected when the ordinary transient postoperative leucocytosis persists. On the other hand, a decrease in the number of leucocytes in these conditions indicates an aseptic fever. Curschmann proclaims that the blood count and leucocytosis are more valuable means of determining the existence of suppuration than the thermometer.—Ed.]

**96. Potassium Nitrate and Nitrite in Chronic Arterial Hypertension.**—It is very important in cases in which the arteries have lost more or less of their elasticity to control the resulting arterial hypertension and avert the rupture of a cerebral artery. The continuous use of .03 gm. of nitroerythrol three times a day will prevent in many persons attacks of angina pectoris, but to ward off cerebral hemorrhage there is need of a drug less powerful but more permanent in its action. This effect is attained by the old-fashioned remedy, saltpeter. The reason why it has been discarded of late years is possibly due to the improved methods of manufacturing which have eliminated the really effective principle. Years ago Brunton was told by a physician with a marked tendency to gout that he had been able to keep himself free from attacks of gout for years while all his relatives suffered severely from them. He attributed his escape to his practice of drinking every morning 1.8 gm. potassium bicarbonate and 1.2 gm. potassium nitrate in a pint of water. He kept it up for thirty to forty years. He had noticed that the saltpeter which he purchased from a powder manufacturer was much more effective than that obtained from the druggist. Brunton had had a similar experience with a patient 65 years old who suffered from severe hemorrhages from the nose recurring several times a day. He prescribed the above combination in a large glass of water

every morning. The effect was like magic. The hemorrhages ceased at once, but when the patient returned to the city, he found that the saltpeter which he bought from an apothecary cost him six times as much as that which he had previously been purchasing from an oil dealer, while it had absolutely no therapeutic effect. This suggested that the cheaper article contained impurities—possibly nitrites—which were probably the effective agents. The prescription was therefore altered to potassium bicarbonate, 1.8; potassium nitrate, 1.2; sodium nitrite, .03. Potassium nitrite would have answered the same purpose, but is less frequently kept in stock. This combination worked the same as that purchased from the oil dealer. The potassium salts are said to have a paralyzing action on the heart. This effect is desirable in cases that require less energetic heart action and increased permeability on the part of the arteries, thus reducing the pressure at both ends. All the nitrites have the property of expanding the small arteries and thus diminishing the blood pressure. Leach has demonstrated that the nitrates have the same property, but act much slower and more gradually. The combination of the nitrates and nitrites therefore regulates the hypertension by moderating the heart action and dilating the vessels, and has besides this, an unmistakable diuretic action which sweeps out of the system certain substances that probably have an irritating and constricting action on the blood vessels. A high blood pressure is found not only in the aged whose vessel walls have become inelastic, but also to a certain extent in kidney affections and especially in the so-called gouty kidney. If this treatment is instituted in time, before anatomic alterations have occurred and while a much accentuated aortic sound is as yet the only symptom, angina pectoris and cerebral hemorrhages can be ward off and the patients long survive.

**98. Attacks of Irresistible Laughing Accompanied by Tonic Contraction of Left Arm.**—Bechterew assumes the existence of an organic affection of the basal portion of the right hemisphere from the symptoms observed in a case which he describes. The attacks began with a brief spasmodic contraction in the left arm, followed by intense pruritus and incessant laughing for nearly a minute. Left hemianopsia and hemioptic pupil reaction were also observed. The impulse to laugh developed as the contraction in the arm disappeared. There was no vertigo nor loss of consciousness. The laughing had the character of the reflex laughing induced by tickling, with none of the characteristics of epilepsy.

**100. Cytodiagnosis of Exudates.**—Patella denies that the lymphocytes found in tuberculous effusions can be derived from the blood as Widal and others claim. They are distinguished by the difference in size, irregular shape, and the regular and intense staining with hematein in inverse proportion to their size. He states that fresh tuberculous effusions always contain endothelial cells and that the nuclei of these cells are liberated as they degenerate and are what have been assumed to be lymphocytes. Almost the only information to be derived from them is in regard to the age of the process, as they are not peculiar to tuberculous exudates and transudates, but are liable to occur also in those caused by the diplococcus.

**101. Fatal Hemorrhage in Chronic Congestion of the Portal System.**—Curschmann has paid especial attention to the coincidence of chronic congestion of the portal system with varicose enlargement of the veins of the lower esophagus and in all his experience since 1876 has never missed it. Thirteen of the patients died from excessive hemorrhages. In 12 the varices were apparently the result of Laennec's cirrhosis; in one they had developed consecutive to a syphilitic affection of the liver. The hemorrhages in these cases were usually abundant and occurred without appreciable traumatism, but the autopsy disclosed an ulceration. In a recent case described at length, a man of 32 with no symptoms of stomach trouble vomited and voided blood occasionally, and the blood indicated pernicious anemia. The liver was small and hard, the spleen enlarged. The autopsy revealed the anticipated cirrhosis and the entire absence of fluid in the abdomen and of meteorism. The source of the hemorrhage was in the stomach, in a varix.

The veins were enormously enlarged, with direct communication with the enlarged left suprarenal and other enlarged veins of the region. This varicose anastomosis between the portal and vasa brevia, which had long preceded the fatal hemorrhage, had been able to compensate the cirrhosis and prevent ascites and distention of the intestines. The cirrhosis in this case, therefore, had existed for a long time and led to a fatal termination, before the characteristic signs of portal congestion had developed.

**102. "Frosted" or Zuckerguss Heart.**—Curschmann described a few years ago a diffuse fibrous thickening of the capsule of the liver which gave it the appearance of frosting on a cake. Eichhorst states that this phenomenon is not confined to the liver alone. He has observed it several times on the spleen and recently on a heart. The appearance of the organ in this case could not be more aptly described than by the term "frosted." The patient was a woman of 40, healthy except for an attack of enteric fever twenty, and a brief attack of acute articular rheumatism five years before. She was suddenly seized with symptoms of insufficiency of the heart muscle, which subsided under treatment in a few days, but recurred again and again, ending fatally in six months. The fibrous thickening was restricted to the epicardium. It evidently interfered with the movements of the heart muscle in both systole and diastole, but the muscle was apparently normal. The patient had probably been addicted to alcohol.

**106. Genesis of Pulmonary Tuberculosis.**—Ribbert presents evidence to sustain his assertion that hematogenic tuberculosis settles by preference at the apices. This point has a defective circulation and is frequently compressed by the premature ossification of the first costal cartilage as Freund has recently pointed out. Still another factor in the localization of the bacilli at this point is the defective ventilation of the lung here, which does not sweep away the bacilli entering the lungs from the blood. Tuberculosis of the bronchial and tracheal glands is in the largest majority of cases derived from the apex of the lung. It is possible but by no means proved that tuberculosis of the apices may be traced to inhalation of germs. It is far more probable that it is of secondary origin. The primarily infected gland does not afford favorable conditions for the proliferation of the bacilli and they die and the gland heals, unless the bacilli are very numerous or the subject is predisposed to tuberculosis. Prophylaxis should aim, therefore, to cure the infected gland before the germs pass into the blood in sufficient quantities to entail the tuberculous process elsewhere, which almost invariably locates at the apex.

**107. Myasthenia and Ophthalmoplegia.**—Gowers describes three cases exhibiting the symptoms which we are accustomed to attribute to myasthenia, weakness of the limbs, moderate exhaustion of the muscles connected with the eyeball, some ptosis and weakness of the other muscles of the eyes, as well as of several of the muscles innervated by the facial nerve, the zygomatic muscles in particular. This caused a characteristic expression during laughing. The symptom of this "nasal smile" not only suggests the diagnosis but explains to a certain extent the pathology, as the muscles involved are those affected in muscular dystrophia. He was able to keep his patients under observation for years and the symptoms maintained their mild character, which speaks against a toxic origin. The results of electric tests of the muscles suggest that the affection is limited to the muscle fibers, and can not be referred to the central nervous system. The fact that the ocular muscles tire so readily coincides perfectly with the similar symptom in nuclear ophthalmoplegia. The writer concludes with the statement that if the affection can be referred to a nervous origin, only the fibrils can be incriminated. None of his patients were cured, but one was much improved by light massage and tonics, especially phosphorus and quinin, alternating with subcutaneous injections of strychnin. The improvement has been maintained for more than two years.

**114. Drunkard's Liver in a Child.**—A little girl was given regularly for four years a small glass of beer—.2 liter—or a wineglassful of wine—.12 liter—every evening, and during the

summer as much beer at the noon-day meal as she wanted. Symptoms developed suggesting either tuberculous peritonitis or atrophic cirrhosis of the liver, and the autopsy confirmed the existence of the latter. The prognosis of such cases is unfavorable if not absolutely fatal. Treatment is usually ineffectual, but occasionally good results have been attained with mercurial inunctions, abdominal massage and prolonged use of Carlsbad water. Beck has collected from various writers 303 cases of cirrhosis of the liver in children, which includes 48 directly traceable to alcohol. The present case was remarkable by the smallness of the daily dose in comparison to the effects.

**122. Mortality from Diphtheria in Germany.**—Mueller presents in graphic form the mortality from diphtheria in Germany during the last twelve years, showing the remarkable lessening of the mortality from this cause since serum treatment was introduced. Statistics covering such a long period and a population of ten millions can not be ascribed to chance or casual circumstances.

**123. Alexins in Milk and in Infant Serum.**—Moro states that his research has established that there are no alexins in milk, and that the alexins in the serum of breast-fed infants are far more powerful than those of the artificially fed. The alexins from the most debilitated breast-fed nursing are very much more bactericidal than those derived from the serum of even robust, artificially-fed infants.

**127. Reflexes in Early Childhood.**—Cattaneo found the plantar reflex and knee-jerk almost constant in infants. They were especially pronounced, as also the abdominal reflex in rachitic children.

**128. Some of the Causes of Intestinal Disorders in Infants.**—Juergenson reports the cases of two infants fed with Soxhlet sterilized milk and healthy when symptoms of sudden illness developed suggesting poisoning. He found that the rubber stoppers of the jars used gave off antimony and sulphur in contact with sour milk. In other cases the trouble was traced to the well water in which traces of nitrates were found.

**132. Puncture of the Pericardium.**—Fraenkel describes two typical cases of pericarditis with effusion to illustrate his claim that the puncture should be made on the right side, from 3 to 3.5 cm. from the edge of the sternum. The veins of the heart are very much enlarged in such cases, and there is usually more or less hypertrophy of the heart, particularly of the left ventricle. Consequently there is great danger of injury from puncture on the left side. The heart does not sink back as the subject reclines, but has a tendency to float on the surface of the fluid, which brings it close to the wall of the thorax to which it may be adherent in some cases. The effusion frequently collects behind the heart and only a small amount can be evacuated by puncture. If the heart beat is perceptible on the left side and there is an area of dullness below it, puncture is permissible. But if the diaphragm is not forced down, the puncture should be made on the right side in the third or fourth interspace at the point of absolute dullness. The heart may be totally displaced to the right, and consequently one must be sure that the area of dullness passes beyond the right parasternal line at least.

**134. Influence of Formaldehyd on the Constituents of the Urine.**—Formaldehyd enters into chemical combination with some of the elements in the urine and disturbs or prevents certain important reactions on the part of the indican, uric acid and acetic acid, pentoses, etc. Hence it should not be added to urine which is to be analyzed.

**135. Treatment of Acute Nephritis.**—Renvers remarks that an unnoticed sore throat, a catarrhal gastrointestinal affection or an infectious disease may be the cause of an apparently spontaneous nephritis. Appropriate treatment of the primary affection will promptly cure the latter. Early serum treatment of a diphtheritic affection, for example, will have a favorable effect on the kidneys, not only preventing nephritis but curing it if already established. In promoting elimination of the toxic substances by the skin and intestines, the saline are the only purgatives at our disposal which do not contain some

elements irritating for the kidneys. Intestinal injections of warm saline solution are also beneficial. The diet should contain carbohydrates and fats to supply the needed calories, and limit the albumin to what is actually necessary, not more than 50 or 60 gm. for an adult not at work. An exclusive milk diet is not advisable as it contains albumin. The milk can be diluted with gruels, etc. As the nephritis subsides the milk can be increased to two quarts a day. Even after albuminuria has entirely disappeared, meats should be added only tentatively to the diet. Vegetables and fruits are not permissible unless the diuresis is abundant. The allowable proportion of albumin should be supplied at first in the shape of pure vegetable albumin. In case the blood pressure is low, hot drinks will be found useful, avoiding those containing meat extractives or alcohol. Digitalis and strophanthus are rather injurious than beneficial if administered with normal blood pressure. Hot drinks of sweetened diluted milk or malt extract with cream, and brief hot footbaths are useful measures, but the only real diuretic, he reiterates, is water.

**137. Treatment of Recent Disturbances in Compensation.**—Instead of prescribing digitalis at once for a patient with dyspnea and other symptoms of disturbed compensation, Klemperer advises temporizing if the symptoms are not threatening. Absolute repose and the reassuring words of the physician, supplemented by small doses of some narcotic, will arrest the reflex suffocation and produce such improvement in twenty-four hours that digitalis will prove unnecessary. The later it is postponed the greater will be the benefit derived when it becomes actually indispensable.

**138. Treatment of Hemoptysis.**—The main point in treatment is to keep the lung quiet. The movements of the affected side should be restricted as much as possible and a bag of sand will be found useful, gradually increasing the weight of the sand from one to five pounds. Klemperer has frequently found that this aided in arresting the hemorrhage.

**139. The Diet of the Aged.**—Food for elderly people should be cut up very fine, preferably with an instrument for the purpose, a "masticator." Their teeth are defective, the muscles engaged in chewing tire easily, and they have little saliva. The best of all food for them is soups, soft eggs, and above all, milk. The old saying that wine is the milk of the aged should be transposed to: Milk is the wine of the aged.

**144. Experimental Lead Poisoning.**—Jores found that chronic lead poisoning in rabbits caused the destruction of the red corpuscles with consequent anemia. The smaller arteries were much dilated, and deposits of blood pigments were noted in the spleen, marrow, liver and kidneys.

**146. Biliary Capillaries in Pathogenesis of Icterus.**—The new stain with which Eppinger has been studying the biliary capillaries is a combination of Weigert's neuroglia stain and the Weigert-Vasale technic.

**151. Experimental Inoculation with Tuberculosis.**—The bacilli introduced into the trachea of rabbits induced first a catarrhal inflammation and then a proliferation of tissue which terminated in the accumulation of giant cells from the breaking down of single cells.

**160. Variolation.**—Mohammedan peoples refuse vaccination, partly from fear of infusing infidel blood into the veins of a "true believer," and partly because the poor quality of vaccine in Oriental countries has prejudiced them against it. Gros has witnessed a large number of cases inoculated with fluid from a smallpox pustule in order to arrest an epidemic of smallpox. It accomplished its end in this respect and the resulting infection was extremely mild. Localized smallpox followed in 25 cases, with no eruption in 36 and only 6 of generalized disease, out of a total of 67. Vaccination afterward was negative. The pustules resembled more those of varicella than of variola. The claim is made that the immunity conferred is more lasting than after vaccination, but Gros knew of one case of infection eight years after variolation. The inoculation is made on the dorsal side of the loose skin between the thumb and forefinger, penetrating into the cellular tissue.

**165. Serotherapy of the Plague.**—Peypers reviews the spread of the plague and quotes an article by a local practitioner in the *Indian Lancet* of March 10, which acknowledges that human science is powerless. "Millions have been its victims and millions more will be claimed as its victims." The optimistic assertions of Europeans, Calmette in particular, that the terrible hecatombs of the middle ages need not be feared at the present day, are criticised by Peypers, who thinks that serotherapy is not proving the anticipated protection.

**169. Enquiry in the Gynecologic Field in Regard to Contagiousness of Cancer.**—Bossi has been investigating for the last ten years the question of contagion of malignant neoplasms. He thinks that exceptionally favorable conditions for contagion are afforded by cancer of the cervix in married women. It usually develops into a comparatively late stage before it is recognized, and the traumatism of cohabitation frequently causes it to bleed. The hyperemia of the parts would also favor contagion. Notwithstanding these and other factors favorable to contagion under these circumstances, he was unable to discover a single instance of malignant disease of the penis among the husbands of the 180 women with cancer of the cervix whom he has had occasion to treat during these ten years. He wrote to the leading gynecologists of Europe and received replies from 38. All unanimously declared that they had never known of cancer on the penis of the husband of any patient with malignant disease of the cervix. Hertaux writes that he has had only 6 cases of cancer of the penis, and none of them could be traced to a woman with uterine cancer. Richelot has never witnessed nor found in science a case of this nature. Fehling replies: "None in twenty-five years of practice." Dermacuay, Bossi states, reports the single instance of cancer of the uterus in the wife in 134 cases of cancer of the penis in his practice.

**170. Hemostatic Action of Endovenous Injections of Calcium Chlorid.**—Silvestri proclaimed in 1898 the great value of the calcium salts in all kinds of hemorrhagic affections, especially scorbutus. It rapidly restores normal coagulability to the blood. He published 13 cases which demonstrated the constant and prompt hemostatic action of calcium hypophosphite in all kinds of hemorrhage. He administered it by the mouth or rectum. He has since applied this method of hemostasis in urgent cases by the endovenous route, and reports four in detail. He injected 100 or 150 c.c. of a 1 per cent. solution of calcium chlorid, repeated in twelve hours if necessary. One patient was a girl of 13 with hemorrhage from the intestines the fourteenth day of typhoid fever. The hemorrhage was arrested in 35 minutes after the injection. Another patient was a woman of 42 with severe menorrhagia which subsided in less than an hour after the injection. The same result was obtained in a case of hemoptysis and in one of hemophilia. The injections failed to arrest the hematemeses in a case of gastric ulcer, and the patient proved rebellious to injections of gelatin later. Zibell announced last year that gelatin contains .6 per cent. of calcium and attributes its hemostatic action to this constituent.

## Queries and Minor Notes.

GARRETSON, S. D., May 12, 1902.

To the Editor:—Please give me the law for medical registration in the state of Washington. H. L. SAYLOR.

Ans.—Diploma from college of at least three years' course and an examination.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

**INTERNATIONAL CLINICS.** A Quarterly of Illustrated Clinical Lectures and Especially Prepared Articles on Medicine, Neurology, Surgery, Therapeutics, Obstetrics, Pediatrics, Pathology, Dermatology, Diseases of the Eye, Ear, Nose and Throat, and Other

Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World. Edited by Henry W. Cattell, A.M., M.D., Philadelphia; John B. Murphy, M.D., Chicago; Alexander D. Blackader, M.D., Montreal; H. C. Wood, M.D., Philadelphia; T. M. Rotch, M.D., Boston; E. Landolt, M.D., Paris; Thomas G. Morton, M.D., Philadelphia; James J. Walsh, M.D., New York; J. W. Ballantyne, M.D., Edinburgh; and John Harold, M.D., London. With Regular Correspondents in Montreal, London, Paris, Leipzig and Vienna. Volume I. Twelfth Series. 1902. Cloth. Pp. 306. Price, \$2.00. Philadelphia: J. B. Lippincott Co. 1902.

**THE OPERATIONS OF SURGERY.** By W. H. A. Jacobson, M.Ch. Oxon., F.R.C.S., Surgeon to Guy's Hospital; and F. J. Stewart, M.S. London, F.R.C.S., Assistant Surgeon Guy's Hospital, and to the Hospital for Sick Children. Fourth Edition, Revised, Enlarged and Improved. 550 Illustrations. Two Volumes: Volume I—Operations on the Upper Extremity; Operations on the Head and Neck; Operations on the Thorax. Volume II—Operations on the Abdomen; Operations on the Lower Extremity; Operations on the Vertebral Column. Cloth. Pp. 402. Price, \$10.00. Philadelphia: P. Blakiston's Son & Co. 1902.

**ATLAS AND EPITOME OF OPERATIVE SURGERY.** By Dr. Otto Zuckerkandl, privatdocent in the University of Vienna. From the Second Revised and Enlarged German Edition. Edited, with Additions, by J. Chalmers DaCosta, M.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia, etc. Second Edition, Thoroughly Revised and Greatly Enlarged. With 40 Colored Plates and 278 Text Illustrations. Cloth, \$3.50 net. Pp. 410. Philadelphia: W. B. Saunders & Co. 1902.

**ATLAS AND EPITOME OF OTOTOLOGY.** By Gustav Bruhl, M.D., of Berlin, with the Collaboration of Professor Dr. A. Politzer, of Vienna. Edited, with Additions, by S. MacCuen Smith, M.D., Clinical Professor of Otology, Jefferson Medical College, Philadelphia. With 244 Colored Figures on 39 Lithographic Plates and 99 Text Illustrations. Pp. 292. Cloth, \$3.00 net. Philadelphia: W. B. Saunders & Co. 1902.

**PHOTOGRAPHIC ATLAS OF THE DISEASES OF THE SKIN.** A Series of 80 Plates, Comprising More Than 100 Illustrations, with Descriptive Text, and a Treatise on Cutaneous Therapeutics. By George Henry Fox, A.M., M.D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, N. Y. Part XI. Philadelphia: J. B. Lippincott Co. 1901.

**SURGERY OF THE RECTUM.** By Charles B. Kelsey, A.M., M.D., Late Professor of Pelvic and Abdominal Surgery at the New York Post-Graduate Hospital. Sixth Edition. Illustrated by 215 Engravings. Cloth. Pp. 402. Price, \$3.00. New York: Wm. Wood & Co. 1902.

**PROCEEDINGS OF THE AMERICAN MEDICO-PSYCHOLOGICAL ASSOCIATION,** at the Fifty-seventh Annual Meeting, Held in Milwaukee, Wis., June 11 to 14, 1901. Cloth. Pp. 333. Published by the American Medico-Psychological Association. 1901.

**PROCEEDINGS OF THE NEBRASKA STATE MEDICAL SOCIETY.** Thirty-third Annual Session, 1901. Cloth. Pp. 343. Lincoln, Neb.: Published by the Western Medical Review Publishing Co.

**TRANSACTIONS OF THE CHICAGO PATHOLOGICAL SOCIETY.** From October, 1899, to June, 1901. Cloth. Pp. 486. Chicago: American Medical Association Press. 1902.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., May 1 to 7, 1902, inclusive:

James K. Ashburn, contract surgeon, leave of absence extended fourteen days.

Charles L. Baker, contract surgeon, from Augusta, Ga., to San Francisco, for temporary duty in the Department of California.

William H. Block, captain and asst.-surgeon, Vols., leave of absence for one month granted.

William J. Calvert, lieutenant and asst.-surgeon, U. S. A., leave of absence for two months granted, to take effect from the completion of his temporary duty at Fort Barrancas, Fla.

Joseph T. Clarke, captain and asst.-surgeon, U. S. A., member of a board in Philadelphia to ascertain and fix the responsibility for any deficiencies or damage to quartermaster's property received at that depot during the present calendar year.

Basil H. Dutcher, captain and asst.-surgeon, U. S. A., leave of absence for four months granted, to take effect on the arrival of Lieut. Clyde S. Ford, asst.-surgeon, U. S. A., at Fort Hancock, N. J.

Charles B. Ewing, major and surgeon, U. S. A., to represent the Medical Department, along with others already thus assigned, at the Eleventh Annual Meeting of the Association of Military Surgeons of the United States, to be held at Washington, D. C. June 5 to 7, 1902.

Clyde S. Ford, lieutenant and asst.-surgeon, U. S. A., from duty at the U. S. General Hospital, Washington Barracks, D. C., to Fort Hancock, N. J.

Joseph H. Ford, lieutenant and asst.-surgeon, U. S. A., from duty at the post of Washington Barracks, D. C., to duty at the U. S. General Hospital at that place.

James D. Glennau, major and surgeon, U. S. A., is relieved from further duty in the Department of California and will repair to Washington, D. C., reporting to the Surgeon-General for instructions.

James C. Gregory, contract surgeon, now at Tunstall, Va., to duty at Fort Myer, Va.

John D. Hall, lieut.-col. and deputy surgeon-general, leave of absence for twenty-one days granted.

Luther S. Harvey, captain and asst.-surgeon, Vols., leave of absence and surgeon's certificates of disability extended one month on account of sickness.

John R. Hicks, contract-surgeon, from Fort Screven, Ga., when relieved by Captain Charles F. Kleffer, asst.-surgeon, U. S. A., will proceed to Fort Wingate, N. M., for duty.

Paul H. Ludington, contract surgeon, now at Omaha, Neb., to report to the commanding general, Department of the Missouri, for duty as attending surgeon in that city.

William J. L. Lyster, lieutenant, asst.-surgeon, U. S. A., from the Division of the Philippines to San Francisco, Cal., for duty with the Hospital Corps Company of Instruction at Fort McDowell, Cal.

Louis A. Molony, contract surgeon, from Cincinnati, Ohio, to San Francisco, Cal., for temporary duty in the Department of California.

William H. Moncrieff, contract surgeon, now at Atlanta, Ga., to report for duty at Jefferson Barracks, Mo.

James R. Mount, contract surgeon, now at Kansas City, Kan., will proceed to San Francisco, Cal., for temporary duty in the Department of California.

Edward L. Munson, captain and asst.-surgeon, U. S. A., detailed a member of a retiring board to meet at the War Department, Washington, D. C.

Joseph Pettyjohn, contract surgeon, now at Vancouver Barracks, is relieved from duty in the Department of the Columbia, and will proceed to his home, Augusta, Ga., for annulment of contract.

John A. Raftier, contract surgeon, now at West Winfield, N. Y., is relieved from further duty in the Division of the Philippines and assigned to duty at Madison Barracks, N. Y.

Anton R. Shier, contract surgeon, now at Burlington, Iowa, to report for duty at Fort Worden, Wash.

Hedley V. Tweedie, contract surgeon, from the Department of the Columbia, when his services can be spared from that Department to San Francisco, Cal., for duty in the Department of California.

### Navy Changes.

Changes in the Medical Corps of the Navy, week ending May 10:

Medical Director W. S. Dixon, detached from duty on the retiring and medical examining boards, Washington, D. C., and ordered to continue other duty.

Medical Inspector W. A. McClurg, detached from the *Kearsarge*, upon reporting of relief, and ordered to the *Olympia*, as fleet surgeon of the North Atlantic Station.

Medical Inspector J. C. Boyd, detached from the *Olympia*, and ordered to Washington, D. C., as member of retiring and medical examining boards.

Surgeon J. M. Steele, detached from Torpedo Station, Newport, upon reporting of relief, and ordered to the *Massachusetts*.

Surgeon H. E. Ames, detached from the *Massachusetts*, upon reporting of relief, and ordered to the *Kearsarge*.

Asst.-Surgeon J. J. Snyder, detached from duty with recruiting party, when discontinued, and ordered to the Torpedo Station, Newport, R. I.

P. A. Surgeon J. E. Page, granted sick leave for two months.

P. A. Surgeon J. C. Pryor, ordered to the *Massachusetts*, May 14.

Pharmacist I. N. Hurd, detached from the *Wabash*, and ordered to the Navy Yard, Portsmouth, N. H.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended May 8, 1902:

Surgeon Eugene Wasdin, leave of absence for seven days from May 2, 1902, under paragraph 179 of the regulations.

Surgeon P. M. Carrington, Bureau order of April 30, 1902, detaching him to represent the service at American Congress of Tuberculosis, revoked.

P. A. Surgeon G. M. Guiteras, relieved from duty at Matanzas, Cuba, and directed to proceed to Philadelphia, Pa., and report to medical officer in command for duty.

P. A. Surgeon M. J. Rosenau, to proceed to Wilmington, Cape Fear Quarantine (Southport), and Beaufort, N. C., as inspector; and inspector of unseizable property at Wilmington and Cape Fear.

Asst.-Surgeon R. H. von Emdorf, upon being relieved by A. A. Surgeon A. B. McDowell, to proceed to Matanzas, Cuba, relieving P. A. Surgeon G. M. Guiteras.

Asst.-Surgeon L. D. Fricks, relieved from duty at Chicago, and directed to proceed to Boston, and report to medical officer in command for duty and assignment to quarters, relieving Asst.-Surgeon John McMullen.

Asst.-Surgeon C. W. Vogel, leave of absence for 15 days granted by Bureau letter of April 18, revoked. Relieved from duty at San Francisco, and directed to proceed to Dutch Harbor, Alaska, and assume command of the service.

Asst.-Surgeon B. J. Lloyd, relieved from duty at San Francisco Quarantine, and directed to proceed to Nome, Alaska, for special temporary duty, assuming command of the service.

A. A. Surgeon Hugh Borford, granted leave of absence for two weeks from May 5.

A. A. Surgeon A. D. Foster, granted leave of absence for fourteen days from May 17.

A. A. Surgeon E. F. McConnell, relieved from duty at Havana, Cuba, and directed to proceed to Nuevitas, Cuba, relieving A. A. Surgeon O. W. Stone.

A. A. Surgeon A. B. McDowell, relieved from duty at Havana, Cuba, and directed to proceed to Santiago, Cuba, relieving Asst.-Surgeon R. H. von Emdorf.

A. A. Surgeon O. W. Stone, upon being relieved by A. A. Surgeon E. F. McConnell, to proceed to his home and await annulment of appointment as acting assistant-surgeon.

A. A. Surgeon Agnes Walker, granted leave of absence for fourteen days from May 17.

A. A. Surgeon W. S. Walkley, granted leave of absence for seven days from May 7.

Sanitary Inspector Lea Hume, granted leave of absence for thirty days from May 1.

Senior Pharmacist M. R. Mason, relieved from duty at San Francisco, and directed to proceed to Dutch Harbor, Alaska, and report to Asst.-Surgeon C. W. Vogel for duty.

Junior Pharmacist F. M. Holt, granted leave of absence for thirty days from May 1.

Junior Pharmacist L. C. Spangler, granted leave of absence for fifteen days from May 10.

### BOARDS CONVENED.

Board convened at the Marine Hospital, Baltimore, May 5, 1902, for the physical examination of certain officers of the Revenue Cutter Service. Detail for the Board: Surgeon H. R. Carter, chairman; P. A. Surgeon J. A. Nydegger, recorder.

Board convened at the Marine Hospital, New Orleans, for the physical examination of such officers of the Revenue Cutter Service as may present themselves, May 12, 1902. Detail for the Board: P. A. Surgeon C. P. Wertenbaker, chairman; Asst.-Surgeon J. W. Schereschewsky, recorder.

Board convened at the Marine Hospital, Boston, May 12, 1902, for the physical examination of such officers of the Revenue Cutter Service as may present themselves. Detail for the Board: Surgeon Fairfax Irwin, chairman; Asst.-Surgeon John McMullen, recorder.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended May 10, 1902:

#### SMALLPOX—UNITED STATES.

Alabama: Birmingham, March 1-31, 11 cases.  
California: San Francisco, April 20-27, 3 cases; Stockton, April 1-30, 20 cases.  
Colorado: Denver, April 19-26, 7 cases.  
Illinois: April 26-May 3, Belleville, 5 cases; Chicago, 5 cases; Galesburg, 4 cases.  
Indiana: Evansville, April 26-May 3, 5 cases; Indianapolis, April 26-May 3, 8 cases; Muncie, April 1-30, 3 cases; South Bend, April 26-May 3, 4 cases; Terre Haute, April 26-May 3, 3 cases.  
Iowa: Ottumwa, March 29-April 20, 18 cases.  
Kansas: Wichita, April 26-May 3, 4 cases.  
Kentucky: Covington, April 27-May 4, 5 cases; Lexington, April 26-May 3, 1 case; Louisville, April 27, 2 cases.  
Maine: Portland, April 26-May 3, 1 death.  
Maryland: Baltimore, April 26-May 3, 1 case.  
Massachusetts: April 26-May 3, 28 cases, 4 deaths; Brockton, 2 cases; Brookline, 1 death; Cambridge, 1 case; Malden, 6 cases.  
Michigan: April 19-26, present at 110 places; Ludington, April 27-May 4, 16 cases.  
Minnesota: Minneapolis, March 29-April 19, 27 cases; Winona, April 19-26, 1 case.  
Missouri: St. Louis, April 27-May 4, 39 cases, 2 deaths.  
Montana: Helena, April 1-30, 4 cases.  
Nebraska: Omaha, April 26-May 3, 30 cases.  
New Jersey: April 26-May 3, Camden, 4 cases, 1 death; Newark, 80 cases, 5 deaths; Plainfield, 6 cases, 1 death.  
New York: New York, April 26-May 3, 54 cases, 14 deaths.  
Ohio: Cincinnati, April 26-May 2, 18 cases; Hamilton, April 27-May 3, 3 cases.  
Pennsylvania: Erie, April 26-May 3, 10 cases; Johnstown, April 19-May 3, 3 cases; Philadelphia, April 26-May 3, 15 cases, 1 death; Pittsburgh, April 26-May 3, 16 cases.  
Rhode Island: Providence, April 26-May 3, 4 cases.  
South Carolina: Greenville, April 19-26, 6 cases, 2 deaths.  
Tennessee: Memphis, April 27-May 3, 9 cases.  
Utah: Salt Lake City, April 26-May 3, 4 cases.  
Vermont: April 27-May 3, Burlington, 2 cases; Rutland, 1 case.  
Virginia: Roanoke, April 1-30, 11 cases, 1 death.  
Washington: Tacoma, April 20-27, 9 cases.  
Wisconsin: Green Bay, April 27-May 4, 3 cases; Janesville, April 27-May 4, 4 cases; Milwaukee, April 19-26, 9 cases.

#### SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, March 16-April 6, 21 deaths.  
Canada: Hamilton, April 26-May 3, 1 case; Quebec, April 19-26, 10 cases; Winnipeg, April 19-26, 8 cases.  
China: Amoy, March 8-27, present.  
Colombia: Panama, April 21-28, 50 cases, 5 deaths.  
Egypt: Cairo, April 1-8, 1 death.  
France: Paris, April 12-19, 5 deaths; Rheims, April 6-20, 7 cases, 5 deaths; Roubaix, March 1-31, 1 death.  
Great Britain: Birmingham, April 12-19, 2 cases; Dublin, April 12-19, 1 case; Dundee, April 12-19, 4 cases; Glasgow, April 18-25, 7 cases, 1 death; Leeds, April 19-26, 1 case; Liverpool, April 12-19, 5 cases; London, April 12-19, 328 cases, 42 deaths; Newcastle-on-Tyne, March 30-April 19, 1 case; North Shields, March 30-April 19, 27 cases; Southampton, April 5-12, 1 case; South Shields, March 30-April 19, 21 cases.  
India: Bombay, April 1-8, 6 deaths; Calcutta, March 22-April 5, 13 deaths; Karachi, March 30-April 6, 3 cases.  
Italy: Bovino, April 12, epidemic; Naples, April 5-12, 10 cases.  
Mexico: City of Mexico, April 13-27, 3 cases; Vera Cruz, April 19-26, 5 cases, 1 death.  
Russia: April 6-12, Moscow, 5 cases, 5 deaths; St. Petersburg, 10 cases, 2 deaths.  
Spain: Cartagena, April 15, epidemic.

#### YELLOW FEVER.

Brazil: Rio de Janeiro, March 16-April 6, 105 deaths.  
Colombia: Panama, April 21-28, 5 cases, 2 deaths.  
Costa Rica: Port Limon, April 14, 3 cases, 1 death.  
Dutch Guiana: Paramaribo, April 1-31, 3 cases, 1 death.  
Mexico: Vera Cruz, April 19-26, 9 cases, 6 deaths.

#### CHOLERA—INSULAR.

Philippines: Manila, March 20-29, 84 cases, 65 deaths.

#### CHOLERA—FOREIGN.

India: Calcutta, March 23-April 5, 255 deaths.  
Turkey: Djiddah, Feb. 19-March 26, 3000 cases estimated, and 1300 deaths.

#### PLAGUE—UNITED STATES.

California: San Francisco, April 20-27, 1 case, 1 death.

#### PLAGUE—INSULAR.

Hawaii: Honolulu, April 19, 1 death.

#### PLAGUE—FOREIGN.

\* China: Peking, April 25, epidemic.  
Egypt: April 7, 1901-April 7, 1902, 382 cases, and 228 deaths.  
India: Bombay, April 1-8, 830 deaths; Calcutta, March 22-April 5, 1239 deaths; Karachi, March 30-April 6, 111 cases, 100 deaths.

## Original Articles.

### NEED OF MUCH MORE ACCURATE KNOWLEDGE CONCERNING BOTH THE IMMEDIATE AND REMOTE EFFECTS OF THE REMEDIAL AGENTS IN GENERAL USE;

### AND THE EXERCISE OF MORE CARE TO AVOID THE COINCIDENT ADMINISTRATION OF ANTAGONISTIC REMEDIES IN ACUTE DISEASES.

N. S. DAVIS, M.D.

CHICAGO.

Perhaps the three most important defects in practical medicine of the present day, as seen both at the bedside and in works on therapeutics and practice of medicine, are: First, failure to fully appreciate the fact that all diseases are deviations from the natural standard of action or of structure in some part or in the whole of the living body, caused by either mental or physical influences, and progressing towards recovery or death in accordance with known laws of vital resistance; second, inadequate knowledge of the physiologic laws and processes that constitute the vital resistance of living bodies to the action of the various causes of disease; third, the imperfect knowledge of the action of many of the most important remedies in the materia medica, and consequently their frequent erroneous or even antagonistic use.

#### THE NEED OF KNOWLEDGE OF VITAL PROCESSES.

A knowledge of the causes of diseases both predisposing and exciting, and the laws governing their action in the living body; an accurate conception of the various morbid processes induced constituting diseases, their natural tendencies and terminations; and an equally accurate knowledge of the modes of action of remedial agents, must constitute the basis of all rational or independent medical practice. It is not sufficient that the physician may know the direct exciting cause of any form of disease, whether it be a microbe, a ptomain, a leucomain, a defective food supply, or a depressing mental condition. He should know also the conditions under which it is produced and propagated; the channels through which it gains access to the living body; the changes it produces in the elements of the blood or of the tissues; and the methods by which it is destroyed or expelled from the living body or induces death. For every pathogenic germ, toxic ptomain, or septic poison that gains access to the living body or any part of it is met by vital processes and conditions by which it is neutralized or expelled, or is multiplied until it destroys the life of the patient or the part in which it is propagated. The vital processes and conditions thus induced

by the presence of the morbid agent to either neutralize or expel the offending cause, constitute the natural vital resistance or immunity, while the active disturbances of both function and structure, consequent on its continued presence and multiplication, constitute the symptoms or active phenomena of the disease. Nearly all the more eminent and philosophic writers on medicine from Hippocrates to those of the present day, make frequent references to the curative powers of "Nature," and most of them repeat the Hippocratic injunction to "follow Nature" in the methods of treating disease. Very few of them, however, have made any attempt to explain what they meant by "Nature" or her processes of cure.

#### THE NECESSITY OF EXCRETION.

The numerous investigations of the last half century, aided by all the instruments and processes devised for securing correct results, have, however, clearly shown that whenever any substance, whether developed within or introduced from without, is present in the living body and is not capable of assimilation and use as food, is either expelled through some of the secreting or eliminating organs unchanged, or oxidized and converted into materials either harmless or capable of more ready elimination. Therefore, oxidation, neutralization and elimination of pathogenic, toxic or disease-producing agents are Nature's chief processes for both preventing and curing disease. And the structures chiefly active in these processes are the bioplasmic or leucocytic cells of both blood and tissues and the various secreting and excreting structures of the body. The same, indeed, that are constantly engaged in oxidizing and eliminating the ordinary products of tissue metabolism and thereby preventing auto-intoxication and death. For every animal, from the lowest in the scale to the highest—from the microbe to the man—perishes if compelled to remain in full contact with its own excretory products. For example, the microbe of vinous fermentation ceases to multiply and soon dies if its excretory product, alcohol, is allowed to accumulate in the fluid surrounding it beyond 14 per cent. And man, representing the highest order of animal life, speedily perishes if retained in an atmosphere surcharged with his own renal, cutaneous and pulmonary excretory products.

#### THE VITAL RESISTANCE.

If it is true that the processes of oxidation, secretion and elimination of waste and disturbing or toxic agents constitute the vital resistance or curative powers of Nature, then in addition to ascertaining the cause or causes of any given disease it is equally important to learn both the channels through which it gains access to the blood and tissues, and the excretory or eliminating organs through which it is expelled.

It is by such knowledge only that we are enabled to direct those remedies that will aid the natural processes of cure with skill and efficiency. With all the facilities for minute and exact investigation afforded by our laboratories of chemistry, biology and bacteriology, supplemented by clinical wards of hospitals, we ought to be able to determine the efficient causes of all acute diseases, and to follow them from their entrance to their exit from the living body; and to see clearly the changes they undergo and the processes by which they are destroyed or expelled.

#### THE MINUTE ACTION OF EVERY DRUG.

With such knowledge, the physician could readily infer the important indications for treatment in every stage in the progress of disease. But to enable him to select the best remedy for fulfilling each indication, he needs the same accurate knowledge of the action of each remedial agent that he uses. Otherwise he is constantly liable to give the same remedy in all stages of the disease, or coincidentally to give two or more remedies that are more or less antagonistic in their effects, and thereby saturate his patient with drugs with but little apparent effect on the progress of disease.

#### VAIN ATTEMPTS TO CLASSIFY DRUGS.

Writers on therapeutics very generally classify or group remedies under names supposed to indicate their most prominent physiologic or therapeutic effects, i. e., stimulants, tonics, sedatives, antipyretics, antiseptics, antitoxins, etc. In doing so they have included in almost every class or group medicines differing widely in their *modus operandi* and in many instances directly antagonistic, i. e., influencing the same structures and functions in opposite directions.

#### PYREXIA AND ANTIPYRETICS.

Only twenty years since the leading writers on practice of medicine claimed that the chief danger to life in the general febrile diseases was the pyrexia or continuous high temperature. In consequence, every remedy that was found capable of reducing the temperature of the body was classed as an antipyretic and given in full doses, at first, regardless of their mode of action, until we had hydrotherapy or bathing of all modes, large doses of quinin, salicylin, antipyrin, antifebrin and a dozen other coal-tar derivatives, all grouped as antipyretics.

While the hydrotherapeutic measures, as sponging or bathing with cool water, increased the efficiency of both circulation and secretion and thereby reduced the temperature by the natural processes of elimination from the skin, kidneys and air passages, all the coal-tar preparations reduced the temperature by diminishing both natural metabolic and excretory functions, and impairing the elimination of waste products and toxic agents. Thus, the first remedies mentioned reduced the pyrexia by increasing the processes of heat dissipation, and the second by diminishing the processes of heat production and at the same time favoring the retention in the system of the toxic agents giving rise to the febrile disease, and thereby increasing both its duration and ratio of mortality.<sup>1</sup>

#### A CONFLICT OF REMEDIES.

Abundant clinical experience soon demonstrated that while the coal-tar antipyretics promptly reduced the pyrexia, they with equal promptness lessened the renal and hepatic excretory functions; impaired the leucocytic and corpuscular elements of the blood and diminished

general innervation. In other words, they depressed or antagonized the very processes and functions that constitute man's vital resistance to morbid influences or the curative powers of Nature, thereby protracting the duration of the diseases they were given to cure. At the same time the judicious use of cold sponging, bathing and packing as antipyretic measures was found to sustain the curative powers of Nature and to lessen the duration of the whole group of febrile diseases. Thus illustrating the necessity of not only knowing that a remedy is capable of reducing pyrexia, but also by what processes it does so, in order to be able to use it with benefit in the treatment of febrile affections.

#### FALSE METHODS OF INVESTIGATION.

It was not until the development of physiologic chemistry and both general and microscopic anatomy, during the nineteenth century, aided by the invention of various instruments of precision, that it was possible to determine the actual effects of either the causes of disease or of remedial agents on the various structures and functions of the living body, in either health or disease. During all the preceding centuries the effects of remedial agents were determined by their visible influences on the various evacuations and on the sensations of the patient. Those that caused increased evacuations were classed as emetics, cathartics, diuretics and diaphoretics, according to their influence on the stomach, bowels, kidneys and skin. Those causing the individual to feel warmer, lighter, more exhilarated, with more frequent heart beat were classed as stimulants or tonics. Those causing less sensibility and pain, with more sleep, were called narcotics or anesthetics, etc.

Relying thus upon the objective and subjective symptoms following the administration of medicines without any of the present instruments and methods of determining their influence on the constituents of the blood; the activity of leucocytes; the oxygenation and decarbonization of the blood; the acuteness of nerve sensibility and rapidity of transmission of impressions; and the force of muscular contractions, then classification of stimulants, tonics, sedatives, and narcotics was based entirely upon the subjective phenomena or testimony furnished by the individual to whom they were administered. As alcohol, ether, camphor, carbonate of ammonia, tea and coffee, in moderate doses produced increased frequency of pulse, exhilaration of mind, a sense of heat, less consciousness of weight or resistance, and an impression that more work both mental and physical could be done, they were universally regarded as both stimulant and tonic. They were given indiscriminately or coincidentally to patients for the purpose of increasing cardiac and nervous force and thereby sustaining both circulation and innervation in the treatment of diseases. Yet when the doses of alcohol, ether or morphin were increased or frequently repeated, they soon began to induce diminished sensibility, loss of co-ordination of muscular action, and impairment of both respiration and circulation, and if continued further, paralysis of the heart and cerebrospinal nerve centers and death was the result. Relying upon the persistent statements of those using them, that they were stimulated and strengthened so long as they were able to talk, and yet showing plainly by their loss of both muscular and mental activity that they were being paralyzed, the inference was drawn that in small or moderate doses they were stimulant and tonic, and in large doses depressing and paralyzing.

This double and apparently contradictory action be-

<sup>1</sup> Address on Medicine before the American Medical Association in May, 1890.

tween small and large doses has been attributed only to medicines of the narcotic and anesthetic classes, i. e., medicines that exert a direct and controlling influence over the sensibility of the cerebral and cerebrospinal nerves, which include the material organs or structures constituting the seat of mental consciousness, or perception of impressions.

#### NEW METHODS OF INVESTIGATION.

It was not until the discovery and practice of anesthesia near the middle of the nineteenth century, and the discovery of the inhibitory influence of the vagus nerve over the movements of the heart, and the subsequent invention of instruments for measuring the time for transmission of impressions and the strength of muscular contractions, that the profession were in possession of the means for demonstrating the real action of medicinal agents called stimulants, tonics, sedatives and narcotics, both in large and small doses, without regard to the opinions or impressions of the persons taking them. Experience in the use of the general anesthetics, ether, alcohol and chloroform, soon showed that their effects were manifested first on the cerebral nerve cells latest in the order of development and connected with the manifestation of the highest and most distinctive faculties of the human mind, i. e., the sense of propriety and self-control, and on the inhibition nerves of the heart, thereby producing mental exhilaration and increased frequency of pulse. Continuing the inhalation, the mental hilarity soon gave place to incoherence and unconsciousness with loss of voluntary muscular movements, but still leaving the involuntary functions of respiration and circulation sufficiently active to maintain life. If the anesthetic was increased beyond this stage, the nerve centers controlling respiration and circulation were paralyzed and death resulted therefrom.

Here we see the same consecutive order of symptoms speedily following the inhalations of anesthetics, as we see developed more slowly by giving successive doses of alcohol or other anesthetics and narcotics by the mouth. That is a stage of apparent mental and vascular excitement while the amount taken is small; passing gradually into dulness, stupor and finally profound unconsciousness as the doses were increased or frequently repeated. Thus apparently confirming the long-standing popular opinion, that in small doses all such agents were stimulating and strengthening, and in larger doses, depressing and paralyzing. But this apparent stimulation of the small doses was soon shown to be only the beginning of the paralyzing influence more quickly felt by the inhibitory nerve structures of both heart and brain, by the application of instruments of precision abundantly confirmed by experience in all the ordinary relations of life. For direct experiments by investigators in different countries have uniformly resulted in showing that persons under the influence of only just sufficient doses to quicken the pulse, create a sense of heat and a feeling of exhilaration, i. e., when the individual generally says he feels better and could do more work either physical or mental, the application of the thermometer proves a lower temperature, and the application successively of other necessary instruments show that the peripheral capillaries are dilated, the systolic force of the heart less, the transmission of impressions slower, the strength of voluntary muscles less, and the mental activity retarded. In other words, all the seeming stimulation of the small doses was only the incipient stage of paralysis affecting the very cerebral nerve cells that are the seat of consciousness, and thereby deluding both the patient and the

physician who relied upon his testimony. The paralyzing influence of larger doses was too manifest to deceive the physician, but not sufficient to undeceive the patient who, when he had taken so much that he could no longer stand up, and it required two men to support him on his feet, the impression was still running through his brain that he could whip them both.

When we realize the all-important fact, that all anesthetic and narcotic medicines or drugs act primarily on the cerebral and cerebrospinal nerve structures in the direction of diminishing the sensibility of these structures, we see clearly why those taking them are incapable of giving correct information concerning their action, or that of any other agents that may be brought to bear upon them at the same time.

#### RESULTS OF LATER STUDY.

The more exact investigations of the last half century have not only proved that all general anesthetics and narcotics, such as alcohol, ether, chloroform and opiates are paralyzing to nerve sensibility in direct proportion to the quantity given, but also, that they at the same time diminish tissue metabolism, the activity of leucocytes, the elimination of waste and toxic agents through the excretory organs, and thereby impair all the vital processes in proportion to the quantity given and the length of time they are used. Therefore, instead of even exerting a true stimulant or toxic effect they directly diminish all the processes that constitute man's vital resistance to toxic or disturbing agents, thereby rendering him more liable to attacks of disease, and less likely to recover when attacked, as demonstrated by the experiments of Drs. A. C. Abbott, Reichert, Laiknau and others, both in this country and Europe. And while the positively depressing and devitalizing influence of alcohol, ether, chloroform, morphin and the coal-tar antipyretics has been abundantly demonstrated by well-devised and carefully executed experiments, aided by all the modern devices for securing accuracy of results, the same is equally shown by the ordinary results of their use by all classes of people and in all climates.

#### LOWERING OF VITAL RESISTANCE.

The history of nearly all severe epidemic diseases, such as influenza, pneumonia, typhoid and typhus fevers, cholera, plague and erysipelas, shows that they more readily attack those who make daily use of alcoholic drinks or other narcotics, and when attacked a much larger proportion of them die, thereby showing unmistakably impairment of their vital resistance. Every authoritative work on either medicine or surgery published during the last half century mentions the habitual use of these same anesthetic and narcotic drugs as important predisposing causes of tuberculosis, septicemia and of fatty and fibroid degenerations of tissues generally. And in every variety of human labor, whether in civil or military life, where total abstainers and even moderate users of these drugs under consideration were required to live and labor side by side with all other conditions the same, the total abstainers uniformly averaged more and better work and yielded much less ratio of sickness and mortality, as shown by the statistics of labor in every country where such statistics are kept: by the annual official reports of the Registrar-General of the British Army, and by the results of life insurance in companies where the total abstainers and the moderate drinkers are designated on their books.

Notwithstanding all the foregoing incontrovertible proofs that the whole groups of anesthetic, narcotic and

internal antipyretic or analgesic drugs, represented by ether, alcohol, chloroform, morphin, nicotin, antipyrin, etc., are true protoplasmic poisons, diminishing nerve sensibility, metabolic and secretory activity, and lessening all vital resistance to toxic agents in proportion to the quantity used, yet they continue not only to be used freely by a large proportion of the profession in the treatment of a great variety of diseases, and still more freely by the non-professional public.

#### EPIDEMICS OF HEART FAILURE.

The active ingredients in most of the "headache powders" and other popular remedies for migraine, neuralgia, insomnia, and general nervousness, belong to the coal-tar group of antipyretics. The same group of remedies were given freely by perhaps a majority of physicians in the treatment of influenza or la grippe, as it has prevailed since the epidemic of 1889-90. And during no previous epidemic of that disease has there been so great an increase of deaths from pneumonia, bronchitis, and so-called "heart failures," nor were they followed by so many severe and protracted sequelæ, characterized by a persistent sense of weariness, loss of muscular strength and nervous energy, frequent neuralgic and rheumatic pains, with impairments of the cardiac, respiratory, and digestive functions and unrefreshing sleep. A very large proportion of such patients readily refer the origin of their troubles to a severe attack of la grippe, often from one to three years previously, during which they took liberal doses of both anesthetic and antipyretic drugs, and have been taking more or less of the same class of remedies to relieve their pains, lessen nervousness, and encourage sleep at night ever since. Thereby they palliate, for a few hours after each dose, their pains and sense of exhaustion, and at the same time perpetuate the impairments of cardiac, respiratory, metabolic and protoplasmic activity, until many of them become permanent invalids, or die suddenly from so-called heart failure.

#### RESULTS OF COAL-TAR PRODUCTS.

During the last fifteen or twenty years the discovery of pathogenic bacteria and their ptomain or toxic products as causes of acute infections as well as some more chronic diseases, has induced nearly all recent writers on therapeutics and practice of medicine to represent heart failure as the chief source of danger instead of the excessive pyrexia of the preceding decade. Hence in their chapters, especially on pneumonia, influenza, diphtheria, typhoid and typhus fevers, etc., they emphasize the danger from this cause, and charge the practitioner to guard against it, even from the early stages of those diseases. Consequently, a group of remedies called cardiac tonics and stimulants is now occupying the same prominent position in practical therapeutics as the antipyretic group did two or three decades since; and, unfortunately, it is made to include some remedies more antagonistic in their effects than were any of those in the antipyretic group.

#### ANTAGONISTICS CLASSED AS SYNERGISTS.

As has been previously stated, so long as the profession were obliged to depend upon the objective and subjective phenomena furnished by the person taking any particular medicine, they called all such as rendered the action of the heart slower, cardiac and arterial sedatives; and such as increased the frequency of the cardiac systoles were ranked as stimulant and tonic. Accordingly, aconite, veratrum viride, strychnin, digitalis, strophanthus, cactus, etc., were all called cardiac and vascular

sedatives; while alcoholic liquors, ether, camphor, carbonate of ammonia, tea and coffee were ranked as direct cardiac and vascular stimulants and tonics. But when the modern processes of experimental therapeutics were applied to them it was soon demonstrated that the strychnin, digitalis, etc., so influenced the cardiac, respiratory and vasomotor nerve centers as to cause the cardiac action to be slower and stronger, and more tone or firmness of the arteries, with deeper inspirations; thereby showing them to be true cardiac and vasomotor tonics instead of sedatives. And as their action was not accompanied by coincident anesthetic influence on the cerebral hemispheres, they were readily transferred to the class of cardiac and vasomotor tonics with alcohol at its head. Consequently, we still find in nearly all recent practical works heart failure is set forth as the chief danger in the progress of all acute infectious diseases, to counteract which early resort should be had to cardiac and vasomotor tonics, of which we are uniformly assured that "alcohol, strychnin, digitalis and strophanthus are the most reliable." Thus placing two remedies at the head of the list, to be given alternately or even simultaneously to the same patients and for the same purposes, that have been demonstrated to be as near absolutely antagonistic in their influence on the cerebrospinal, vasomotor, metabolic and excretory functions as any other two remedies to be found in the materia medica. The one, alcohol, diminishing all the functions named, while by its anesthetic effect it renders the patients more quiet and less conscious of either weakness or pain; and the other, strychnin, increasing them, and thus leaving the physician to wonder why the patient tolerates so large an amount of medicines with so little apparent effect. Is it not fully time that such inconsistent medication should be avoided?

#### TRANSIENT MONOCULAR BLINDNESS.\*

WILLIAM CAMPBELL POSEY, M.D.

Professor of Diseases of the Eye in the Philadelphia Polyclinic and School for Graduates in Medicine.

PHILADELPHIA.

Apart from the momentary blurring of vision from a tired ciliary muscle, or the partial blindness which accompanies migraine, or the periodic dimness of sight which is so frequent a precursor of glaucoma, transient loss of vision limited to one eye is very uncommon.

The attention of the writer was first called to this symptom some years ago by a patient, an elderly clergyman, who was brought to the office in a great state of perturbation by a friend, on account of the sudden loss of sight in the right eye. The blindness was complete for about fifteen minutes and then began to clear, so that by the time the office of the writer was reached, about half an hour after the commencement of the attack, sight was fully restored. A careful ophthalmoscopic examination was at once made, but failed to reveal any cause for the blindness, other than changes in the retinal vessels, which indicated a high degree of arterial sclerosis; thickening of the walls of the arteries and veins and too pronounced a light reflex upon them. The veins were slightly enlarged and pulsated upon the disc. Precisely similar changes were observed in the left eye. There was nothing to note externally beyond a pronounced degree of arcus senilis in both eyes. After the correction of a moderate amount of far-sighted astigmatism, the vision of both eyes was brought to normal.

\* Read before the Section in Ophthalmology of the College of Physicians in Philadelphia

Upon questioning the patient it was ascertained that a similar attack of blindness had occurred in the same eye three weeks previously, the loss of sight at that time having persisted about ten minutes. Since there appeared to be no ground for alarm so far as the immediate safety of the eye was concerned, the fears of the patient that he would lose his sight were allayed and he was dismissed with the request that he see his physician at once for a thorough examination of his physical condition, as it occurred to the writer that the blindness was probably of a vascular origin. The patient was the subject of rheumatoid arthritis of marked degree and it was thought not unlikely that there had been changes in the blood vessels induced by this disease. Three days later he returned a second time, even more anxious than before, as he said that the blindness had returned for the third time and that it had persisted, though with intervals of remission, for five or six hours. An ophthalmoscopic examination was at once made with a negative result. His physician reported his kidneys and heart to be normal and his general condition excellent, considering the ravages of the rheumatoid arthritis, which had produced extensive deformities in the small joints. His diet was curtailed and he was placed upon active saline treatment. Two years have now elapsed without a recurrence of the blindness. To sum up briefly: all three attacks occurred in an interval of less than a month; the blindness always affected the right eye; the loss of sight was sudden and complete, the patient being unable to see a lighted match before the eye; the vision of the fellow eye was unaffected. Recovery of sight was rapid, beginning in the temporal field, and was preceded by the appearance of phosphenes. The attacks were not accompanied by headache, nausea or other general symptoms and so far as the patient knew were not precipitated by any unusual activity of mind or body.

Another case of the same nature, a lawyer, aged 30, came under the observation of the writer 7 years ago on account of twitching in the lids after prolonged near work. He had had headache but rarely and had never experienced any former difficulty with his eyes. Examination revealed fibrillary twitching in the orbicularis of both eyes, more marked on the left side, especially when that eye was made to fix. Vision and accommodation were normal in both eyes. At 5 meters esophoria equaled 2 degrees; at 40 cm. there was exophoria of 2; hyperphoria was absent. The eyegrounds were normal. Refraction under mydriasis showed a moderate degree of farsighted astigmatism in both eyes. Under a partial correction of this error the twitching subsided in large measure, but it was found that a full correction was necessary to cause its full disappearance.

About a year after he had worn the correction the patient returned, saying that he had noticed on two occasions that the lower half of objects became suddenly obscured. No headaches followed the loss of sight, though he thought he remembered seeing a play of lights before the eyes. He was unable to say whether both eyes were affected or not. A month later he had another attack in which the right eye became absolutely blind for fifteen minutes. There were no other motor or sensory symptoms, and headache and nausea were absent. Three months after this, after reading, he noticed a dark spot, the size of a fifty-cent piece, over the right eye, when he regarded the flame of a lamp. The spot for a time was directly in the center of vision and then became eccentric. After persisting half an hour, this phenomenon passed slowly away. One month later the upper half of

his right eye became totally blind for fifteen minutes. Vision was then undisturbed for six months when the lower half of the same eye became blind for five minutes. Nine months later the right eye became totally blind again, the loss of vision beginning in the lower part of the eye. In writing of this attack the patient expressed himself as follows: "I was standing on a street corner talking to Mr. M. when a dimness came over the lower part of the right eye. Thinking my glasses were fogged, I removed them for the purpose of cleaning them, when I found that the trouble was in the eye. The sight became rapidly dimmer, so that in a few moments I could hardly distinguish light with that eye. I was feeling perfectly well at the time, and after the vision cleared, which happened in a few moments, I resumed the conversation." A week later he had another attack of dimness in the same eye, the loss of sight being more marked in the upper nasal field. During the last three years he has had several other attacks of blindness in the right eye, the loss of vision usually beginning in the lower part of the eye.

As this patient lived at some distance from the city the writer has never had an opportunity of making an ophthalmoscopic examination during an attack, but in the interval the findings are negative. This patient, though young and vigorous, led a sedentary life, has had several attacks of rheumatic fever and came of a gouty family.

About 16 months ago the writer had the opportunity of studying a third case, that of a man aged 50 years, who consulted him on account of a sudden loss of sight in the right eye. He said that the eye was so blind that he could not see his hand even when it was held close to the eye, for at least one hour, and that during still another hour the fog was so thick that he could barely distinguish large objects. There was no headache or other accompanying symptoms. Since then he has had six other attacks, but not always in the same eye; the third and the last two occurring in the left. All of the attacks came on after taking a nap in the middle of the day. The second and third attacks lasted 30 minutes, and the last three but five minutes. The optic nerves in both eyes were somewhat grayer than is usual, but central and peripheral vision were unaffected. The retinal vessels showed no changes beyond a slight fulness and tortuosity of the veins. So far as could be ascertained, the patient was in perfect health.

In addition to these three, the writer remembers two other cases of a similar nature. One of these, a young woman who was epileptic, said that quite independent of her epileptic seizures she had had transient attacks of blindness in one eye which lasted from two to ten minutes. Loss of sight was sudden and complete; both eyes had been affected but never at the same time. No other symptom accompanied the blindness. Her epileptic attacks were without visual aura.

In the remaining case, that of a young married woman twenty years old, the blindness, which affected the right eye only and lasted from five to ten minutes, had appeared several years previously and had recurred on an average of once a month. The patient had had several miscarriages and was said by her physician to suffer from uterine disorder. There seemed to be no connection between the loss of sight and menstruation. There was a large patch of choroiditis in her left eye, which looked as though it might have been of a vascular origin.

Though cases of this nature can not be rare, for some curious reason, except where the loss of vision has oc-

curred in connection with embolus and thrombosis of the central artery of the retina, transient attacks of blindness in one eye have escaped description in the textbooks, and have received study by but a few. It so happens, however, that these few have all been leaders in the ophthalmologic world, so that the observations which have been recorded are all instructive and comprehensive.

Loring in 1874 was the first to make any extensive communication upon the subject of transient attacks of blindness, although Alfred Gracfe, Hedaeus, Rothmond, Secundi, and others had reported isolated cases, where this symptom had occurred in connection with excessive reduction in the diameter of the retinal arteries. Loring based his study upon the observation of five cases, in all of which symptoms previously ascribed to embolism of the central artery of the retina were present. This origin of the blindness, however, he disputed and concluded that, in the train of symptoms classed under the title of embolism, too much significance had been given to the stoppage of the circulation by the lodgment of a plug formed at a distance from the eye, while not enough stress had been laid upon the mechanical actions regulating the supply of the blood within the eye, as well as upon the condition of the walls of the vessels themselves and their contents. In explanation of the blindness, he says: "Might not the blindness be the final result of a series of processes which had been smouldering for some time and which had ended in a stoppage, or at least in a reduction of the circulation. This sudden shutting down of the circulation occurs in other parts of the body and why not in the eyes? A rapid transudation of serum from the capillaries and small vessels might so interfere with the fluidity of the blood as to render it unfit for circulation, or the stoppage might be brought about by some antagonistic condition of the walls of the vessels themselves. In a membrane so delicate as the retina, and one which the simplest experiment proves is so absolutely dependent upon the circulation for the performance of its functions, the slightest disturbance might seem to overthrow the equilibrium of the circulation and thus bring on, just as Donder's experiment does, almost instantaneous blindness."

A few years later (1879), Nettleship added largely to our knowledge of the subject by contributing two cases of repeated paroxysmal failure of sight, in connection with heart disease. He offered the hypothesis that the loss in vision was due to some permanent local disease of the ophthalmic artery or its branch to the retina in conjunction with a feeble stream of blood entering the eyes as a consequence of cardiac trouble.

In 1884 Priestley Smith reported a series of cases, which supported in the main the conclusions arrived at by Loring and Nettleship. The chief point made by him, however, was that permanent, as well as transient attacks of loss of sight from diminished blood supply to the retina, are usually of thrombotic origin and may occur in persons other than those who have organic disease of the heart. In support of this theory he reported a number of cases where he thought the blindness was due to disease of the sexual organs and explained the pathologic sequence in these by reflex disturbance of the circulation in the brain and retina through cardiac inhibition: great reduction and slowing of the blood stream in the retinal artery and finally thrombosis; this latter being strongly favored by anemia and feebleness of heart.

The next communication of importance upon the sub-

ject was not until 1897, when Wagenmann reported a case before the Congress at Heidelberg, of repeated attacks of loss of sight in one eye, which finally culminated in the eye becoming absolutely blind. He attributed the blindness in this case to a spasm of the central artery of the retina, and thought that this was secondary to arteriosclerosis, of which there was ophthalmoscopic evidence.

All of these authors, therefore, attribute the loss of sight to some disturbance in the vascular supply of the eye. Indeed, in the absence of any pathological findings in the fundus after attacks of blindness such as have been described, it is natural to impute the loss of vision to some spasmodic affection of the vessels, the spasm not being maintained long enough to cause any permanent change in the tissues.

In all of these cases, the blindness, though complete for a time and recurring in several instances over many years, was transient, and the vision, after being suppressed for a varying interval, returned. It would appear from this that such attacks of blindness are not to be dreaded, that they are not deleterious to the eye and that they have no significance other than the slight annoyance which they occasion at the time the vision is affected. The prognosis, therefore, should apparently be excellent. The surgeon, however, who would not give a guarded opinion in this class of cases would commit a grievous error, for it sometimes happens that the blindness which had before been transient becomes permanent, and as there is no way to differentiate the cases in which this unfortunate result occurs from those in which the loss in vision is only transient, it is wiser for the surgeon not to commit himself as to the final result. Of particular interest in this connection are two cases which have recently come to the attention of the writer. The first, J. L. W., aged 40, a manufacturer, consulted him on January 13, this year, on account of the sudden loss of sight in his right eye two days previously. The patient said that 10 years ago while sitting at the table eating, he suddenly became totally blind in both eyes; that this condition persisted for two or three minutes, vision slowly returning at the end of that time. His wife corroborated this statement and added that, with the exception of the disturbance in vision, the patient appeared perfectly well: his face was neither blanched nor suffused, nor did he complain of feeling faint or giddy. At varying intervals after this, he had spells of double vision, one object being higher than the other. The diplopia would last about five minutes, coming on without apparent cause, and was usually manifested when regarding distant objects. These attacks were not associated with nausea or other general symptoms and occurred every week or so. Eighteen months ago, these attacks ceased and he began to have spells of blindness in his right eye. These came on suddenly and lasted but a few minutes. At times the loss of sight was complete and at times but partial. There were 15 or 20 attacks in all. He was never conscious of headache, nausea or other unusual sensations at the time of the attack. The patient was a large, finely developed man of irreproachable habits, he had always been well, save for vague rheumatic pains in his back and shoulders some years previously. His bowels were regular and an examination of his urine showed his kidneys to be normal. His heart was also normal, though his family physician, Dr. U. G. Heil of West Philadelphia, who referred the case to me, stated that there was evidence of cardiac hypertrophy. About 10 years previously, at the

same time that he had noticed the first interference with his vision, he began to have curious smothering sensations in talking, as he expressed it, as though there were a stiffness of his jaws. This was always exaggerated by the embarrassment occasioned by talking to a number of people.

When inquiry was directed particularly to the loss of vision for which he consulted the writer, it was elicited that the blindness had been preceded by a few minutes of flickering, but that it had then become complete and so persisted for 6 or 8 hours, when it began steadily to improve, until it equaled, as it was ascertained at the examination, counting fingers in the upper part of the field at one-half meter's distance.

As was expected from the history, the ophthalmoscope revealed all the signs of a serious interruption in the circulation of the retina. The optic nerve was swollen and its edges obscured, particularly the upper temporal. The retinal arteries and veins were much reduced in size, particularly the superior branches and the veins in this region were twisted and cordlike. The retina was hazy and swollen above and in the papillo-macular region. The lymphatics of the head of the nerve were full. As was indicated by the field blank, that portion of the retina supplied by the superior temporal and the superior macular branches of the retinal artery was blind. The left eye was normal, there being no unusual manifestation in the fundus, vision equaling 5/5.

A diagnosis of thrombosis, or perhaps merely of spasm of the central artery of the retina or of its superior branch, was made and the patient was placed in bed upon active treatment, with a view to reestablishing the circulation in the retina. Gentle but firm massage movements were made upon the globe, the bowels were freely opened and mercury and potassium iodid were administered in large doses. The vision improved gradually, so that at the end of a few days it equaled 5/40. After this treatment had been persisted in for three days and the vision was slowly improving, one day, shortly after eating, the patient again became suddenly and completely blind in his right eye for several minutes. This was due, in the opinion of the writer, to a spasm in the vessel, and indicated in all probability that the structural changes which had occurred in the retina were possibly due to that cause also, without a thrombosis having necessarily formed in the vessel. The patient has been out of bed now for several weeks, walking about and attending to his business; vision is slowly improving, but as is to be expected, the loss in the field still persists.

The second case occurred in the practice of Dr. Julian C. Dewey, to whom the writer is indebted for the report. In this instance the patient, a healthy man, aged 39, had had repeated attacks of blindness in the left eye since he was 8 years old, the loss in vision lasting from five to ten minutes. The attacks had happened so often, however, that the patient had become quite accustomed to them and their appearance had long ceased to occasion him any alarm, as from his past experience he judged that the dimness would soon pass away. A short time ago, however, he suffered another attack, apparently quite similar to the many which had preceded it, but this time, to his great alarm and surprise, the vision had failed to clear and the blindness persisted. He hastened to Dr. Dewey for relief, but without avail, as the ophthalmoscope, which up to this time had revealed nothing

abnormal, showed all the evidences of embolus of the central artery of the retina.

An observation of very great interest in connection with these cases, both from pathologic and physiologic standpoints, is one recently made by Leber, of a case of monocular blindness where there were all the ophthalmic signs of embolus but in which the microscope failed later to reveal any evidence of either embolism or thrombosis. Leber attributed the blindness and the pathologic findings to long-continued spasm pure and simple. The course of both of these cases, until the final attack came and vision was hopelessly lost, was precisely analogous to the apparently innocent group of transient blindness. It is evident, therefore, that the prognosis in all of these cases of transient blindness should be most guarded, as it would appear impossible to predict what the outcome of any one of them might be, whether the blindness be due to spasm and be always transient, whether it be due to a forming embolism which finally destroys the sight by shutting off the blood supply entirely, or whether the same fatal result is attained as in the case reported by Leber, by long-continued spasm, without microscopic change in the vessel walls.

In view of the uncertainty regarding the nature and outcome of these attacks, it is of the greatest importance to prevent a recurrence of them, by combating any tendency towards endarteritis, as it is probable that the spasm in the walls of the vessels is induced by such a process. It has long been a recognized fact that iridectomy, by causing a dilatation of the blood vessels, reduces intraocular pressure. This operation has accordingly been performed in a number of cases of transient monocular blindness with a view to preventing subsequent permanent blindness. Wagenmann would have it performed in every case of this nature. In view of the uncertainty regarding the cause and the course of these cases, it does not seem proper to the writer to subject an eye, which may remain permanently healthy, to an operation which in a certain proportion of instances, no matter how skilfully performed, renders the eye useless for visual purposes. He would, however, insist upon a treatment and a regimen to combat arterial sclerosis. At the time of the attack, the value of nitrate of amyl has been proven, and gentle but active massage of the eye should always be essayed.

## PERFORATING WOUNDS OF THE EYEBALL AND SYMPATHETIC INFLAMMATION.\*

H. GRADLE, M.D.

CHICAGO.

Penetrating wounds of the eyeball constitute a fair share of ophthalmic practice. Where mechanical industries expose workmen to accidents, these injuries may represent nearly 5 per cent. of eye patients. Injuries of this kind are always so serious that the surgeon necessarily feels a grave responsibility until the healing is complete. Every penetrating wound is to be considered from three aspects, viz.: 1, the mechanical consequences; 2, the presence or absence of a foreign body, and 3, the question of infection.

### THE MECHANICAL CONSEQUENCES.

Eye injuries are peculiar in their immediate results, for nowhere else in the body are so many separate tissues of distinctive individuality crowded into so small a space. A wound which perforates the cornea allows

\* Abstract of lectures delivered at the Northwestern University Medical School, with omission of the more elementary details.

the aqueous humor to escape at once, whereby the anterior chamber becomes emptied. The edges of a small and linear wound will adhere sufficiently to allow a refilling within hours, or even less. Larger or irregular wounds may not permit even a temporary reunion for several days. The emptying of the anterior chamber is by itself a transient disturbance, but other mechanical complications are very likely to occur.

As a protection against threatening iritis, the pupil should be kept wide by atropin in every instance of an ocular wound. The eye should be protected from light by a shade and rest of the other eye enforced. A bandage is of object only where a prolapse of iris or vitreous body is feared; otherwise, it is at the best unnecessary. In the case of a diseased and secreting conjunctiva, a retentive bandage may do harm by favoring infection.

Any wound, unless it is strictly central, relatively small or linear, is apt to allow the iris to become entangled. If this incarceration extends only into the internal lips of the wound it causes merely a displacement of the pupil, a trifling disfigurement and perhaps some blurring by a change in the corneal curvature. Much more serious is a prolapse of the iris into a gaping wound or a protrusion beyond it. This always means delayed healing with irritation for at least a period of weeks, and permanent astigmatism even in case of uncomplicated healing. An iris prolapse is besides apt to invite infection. Even if the eye recovers from this at the time, it is in danger of reinfection at some future period. A noticeable number of eyes with healed iris prolapse are lost later by microbic invasion of the scar and entrance of the parasites into the interior through the entangled iris. Every effort should therefore be made to reduce the prolapse of the iris, if seen within the first 36 hours, before the iris has become adherent in the corneal wound. The protruding tag is snipped off clean, as in an iridectomy and the stump in the wound is gently pushed in with a blunt probe if it does not retract itself. As a rule, this can be done under cocaine, especially when aided by suprarenal solution. But if the patient's sensitiveness or timidity require it, it is better to narcotize than to leave even a partial entanglement. Oculists are less positive what to do when an iris prolapse is seen after adhesions have formed. After about the third day it is generally not possible to reduce the iris out of its entanglement. A small prolapse without infection may be allowed to cicatrize. A larger protrusion or a bulging of iris tissue through the gaping wound is probably best cut off whenever seen. The slightly increased risk of infection at the time is more than outweighed by the reduced possibility of mechanical mischief and of later infection.

Whenever an implement perforates the cornea, an advance of but 2 to 3 mm. beyond brings it into contact with the lens. Every injury to the capsule of the lens results in cataract. Whatever portion of the lens substance is exposed to the aqueous humor becomes opaque. If the rent in the capsule is minute or linear it may close speedily and the opacity remain localized—sometimes, though rarely, localized enough to permit good sight. A capsule wound, however, which does not close leads to swelling and opacity of the whole lens. If the rent is large enough the cataract will ultimately undergo a spontaneous cure by absorption of the entire lens. This requires at least ten weeks, often more, and can be completed only as long as there is no central core of lens substance sufficiently hard to be called a nucleus. Complete absorption is not to be depended upon after

about the 20th to 25th year of life, although it may sometimes take place as late as the 40th year (especially in myopes). During the period of swelling and of absorption of the lens the eye is slightly irritated and sensitive. Very rapid swelling of the lens can cause iritis or even glaucomatous symptoms, viz., hardness of the eyeball with considerable pain, particularly in adults. In such an event it is the best policy to allow the lens to escape through a corneal incision. But in the absence of urgent symptoms it is generally preferred to let the cataract alone until the reaction to the injury or the accompanying infection has subsided and to operate subsequently upon a quiet eye.

Escape of the entire lens through a wound occurs very rarely in the case of perforating accidents unless the whole eyeball is torn open. It is, however, not so uncommon as the result of blows causing a rupture of the ocular tunic. Such a rupture from blunt violence takes place, as a rule, through the thinnest part of the sclera just behind the corneoscleral junction and parallel with the latter. The resulting wound may permit an escape of the entire lens. If the conjunctiva is torn through the lens is lost, but occasionally the intact conjunctiva confines the lens outside of the sclera. A rupture in this region is apt to allow the iris to protrude.

Cuts through the sclerotic coat may permit protrusion of the ciliary body and escape of vitreous humor. Injuries involving the ciliary region have always been especially feared on account of the liability to infection and the probability of its persistence. Loss of vitreous substance to the extent of more than a few drops is never quite indifferent. A moderate loss may lead to later shrinkage with detachment of the retina. A wound of sufficient size to permit the escape of about one-half of the vitreous leaves a poor chance for the preservation of a useful or even a quiet eye. If there is any intraocular hemorrhage or displacement of the lens together with extensive loss of vitreous, the better plan is to remove the eyeball. When a sharp tool perforates through the sclera into the vitreous body a localized opacity will usually occur in the injured part of the vitreous, visible with the ophthalmoscope. Such an opacity, if not due to infection, disappears ultimately, leaving scarcely a trace.

Wounds in the sclera should be closed by sutures put through the conjunctiva, after cutting off any lacerated or protruding tags of tissue. No attempt should be made to disinfect the wounds by chemicals, since thorough tests have shown that this is an impossibility, while the irritation by the disinfectant may prove injurious. The closure by sutures gives a fair guarantee against late infection, which undoubtedly takes place many a time, as shown by the occasional late inflammation following unprotected wounds. A very useful protective measure in the case of wounds of the cornea or corneo-scleral junction is the closure by means of conjunctival flaps as taught by Kuhnt. A flap of conjunctiva with broad pedicle, or sometimes merely an undermined bridge is dissected off peripheral to the wound and slid over the latter so as to cover it. The flap is fastened by delicate sutures, wherever feasible, so as to stretch across the wound. No union takes place between the conjunctival flap and the uninjured corneal surface and hence no opacity need be feared. The area of subconjunctival tissue left exposed by the displacement of the flap heals by granulation with very little irritation and without any risk. The operation is, however, a delicate one.

## FOREIGN BODIES.

In the case of any wound of the eyeball, the fundamental question to be raised at once is: whether a foreign body has entered the eye. The answer may be furnished positively by the history one way or the other. If a foreign body is suspected, it is always desirable to see it. If still within the anterior chamber it is directly visible unless covered by blood or later on by an exudate. If caught in the lens it can be seen through the well dilated pupil unless the lens opacity hides it. When back of the lens it is seen on ophthalmoscopic inspection unless it is close to the ciliary region or covered by opacity of the vitreous. The latter lesion itself is strongly suggestive of a foreign body, provided the opacity is not the result of an infective choroiditis. When a foreign body can not be seen its presence can be determined with considerable certainty by means of an x-ray photograph in the hands of an expert. Even glass is sufficiently opaque to cast a shadow, provided the splinter is not too minute. Metal chips can be recognized almost infallibly in this manner, always providing the expert has the necessary technical experience. The foreign body can be localized to some extent by taking two views in different planes, but this phase of the problem is not yet perfected. Recent personal attempts to take two plates with different positions of the x-ray tube and stereoscopic examination of the pictures have led to very encouraging but not yet completed results.

Foreign bodies of iron or steel can be detected also by their attraction of a delicately-suspended magnetic needle. An instrument based on this principle—the sideroscope—is of decisive value in such cases. Its advantage over the x-ray photograph is its instantaneous readiness, without loss of time. On the other hand, it is so sensitive that it requires careful adjustment and hence is available only to the few who possess it as a pre-arranged, permanent fixture.

A foreign body which has not done much mechanical damage still threatens the eye if it carries germs into the tissues. We can only expect red-hot chips or shot and fragments from the interior of metals to be sterile; all other foreign bodies are, as a rule, contaminated. It is general surgical experience, and true of the eye as well, that the presence of a foreign body interferes with the normal tendency to recovery from infection. The instances in which an eye harboring a foreign body overcomes an infection and becomes quiet are so rare that we can not look forward to such an exceptionally lucky event when inflammation has followed the entrance of some fragment. Moreover, even when this has happened it is not uncommon to observe another inflammatory attack at some future time after a quiet interval of months or years.

Sterile foreign bodies are often tolerated by the eye, if not too large, at least for a time. In the case of sterile iron chips, Hirschberg has learned that 30 milligrams is about the largest weight that the eye is likely to retain without ruin. Chips of 150, or at the most, 180 milligrams are pretty sure to damage the eye mechanically beyond hope, unless extracted at once. Even immediate extraction does not save an eye if the splinter exceeds this weight. Smooth shot is apparently better tolerated than irregular chips. I have personally known two instances in which shot was retained with useful sight. Sterile foreign bodies are sometimes retained with very little gross change around them. In most instances, they become hidden by a capsule of connective

tissue. There are many records of eyes in which foreign bodies were tolerated for long periods of time, until finally a reinfection occurred, sometimes due to slight traumatism. It can be safely asserted, however, that an eye which contains a healed-in foreign body does not endanger the fellow eye as long as there is no externally visible irritation.

Some sterile foreign bodies will ruin the eye by their chemical action. Copper, for instance, in the form of percussion caps, produces an aseptic inflammation with thick, purulent exudate. Iron is sometimes borne indefinitely without reaction, while in other instances it causes characteristic changes known as siderosis. The iris turns rusty brown in hue, especially noticeable when originally light-colored. Chips in the lens may cause opacity with yellowish-brown stains. If the fragment of iron is behind the lens it can lead to localized opacities in the vitreous bodies which appear ophthalmoscopically like minute tufts of white cotton and which may ultimately result in retinal detachment. Most interesting, however, is the direct chemical action upon the retina. A chronic degeneration of the nervous elements takes place with increase in the supporting tissue of the retina. The vessels become sclerosed and change into bloodless white cords. This degeneration starts in the area where the iron chip is lodged, and hence the resulting blindness begins by extinction of the part of the field of vision corresponding to the site of the chip. This toxic effect of iron was permanently arrested in an instance of my own by extraction of the foreign body. As far as the changes have gone, however, they are of a permanent character.

In the case of a fresh injury the foreign body should be extracted at once. Every hour of delay increases the danger of infection. There are many instances in which prompt extraction might have saved vision and prevented inflammation, whereas successful removal of the chip the following day was too late to avert disaster.

Iron or steel can be extracted by means of a magnet with rare exceptions. Removal of non-magnetizable bodies is much more difficult and uncertain and the number of successes on record is small. As a rule, a non-magnetic can only be seized when it is visible in the anterior chamber or when well recognizable with the ophthalmoscope. If the foreign body is beyond reach, the chances of its quiet retention are so small and the dangers of destructive inflammation or even sympathetic extension so large that enucleation should always be done. It is only in the case of smooth (and probably aseptic) shot that delay for a few days is justifiable in order to see whether aseptic encapsulation will take place.

If the patient is not seen until infectious inflammation has begun, an attempt may still be made to save the eye by extraction of the foreign body, provided not much over a week has elapsed since the accident, and provided the inflammation has not reached a degree which has practically destroyed the possibility of a useful eye. The specter of sympathetic loss of the other eye looms up whenever we deviate from these rules. This danger is so formidable that it must be understood by the patient that enucleation must be done if unmistakable improvement does not follow the extraction within three to four days.

When a foreign body is retained by the eye without irritation, the patient should be told of the possible danger. The slightest irritation of the injured eye must be a warning to him to consult an oculist at once.

If a foreign body, especially an iron chip, has begun its destructive chemical influence, there may not be danger of sympathy to the other eye, but the injured eye will ultimately be lost. Hence the magnet extraction is imperative.

The results of magnet extraction have varied so much in the hands of different surgeons and according to the time of operation that general statistics are misleading. Chips which are retained by a quiet eye are almost always extracted successfully without further damage. In fresh injuries seen before infection has developed, extraction has saved more than one-third of all eyes with good vision, about one-third without useful sight, while less than one-third required later enucleation. In proportion as we select for statistics the cases with smallest chips and seen earliest after accident the results improve above these averages, while larger foreign bodies and delay diminish the chances. When infectious inflammation has begun the chance of saving the sight or even the eyeball is very much poorer. But since without extraction eyes seen at this period are almost invariably lost, even the reduced chance should not deter from an attempt at extraction, provided previous delay and the height of inflammation do not render the danger of sympathy too formidable.

This is not the place to discuss the technical details of magnet extraction. Hirschberg's electro-magnet is the preferable instrument on account of its availability and low cost. In the case of foreign bodies not perfectly accessible to the eye or to the ophthalmoscope, the giant magnet of Haab (or any of its modifications) may be successful where the smaller magnet might fail, or may accomplish the same end with less damage to the tissues. But the formidable installment of this big instrument and its great cost, will limit it to the practice of those few who expect such cases in larger numbers.

#### INFECTION OF EYE WOUNDS.

Apart from its immediate consequences the ultimate prognosis of any wound of the eyeball hinges entirely upon the occurrence or absence of infection. If no infection takes place, the damage done at the time is practically the ultimate damage.\* A non-infected wound causes no prolonged suffering and disability and involves no danger of sympathy to the other eye. The irritation produced by a trauma without infection reaches its climax within hours, or a day or two at the most, and then begins to subside. The visible vascularity is but moderate and pronounced only in the area next to the wound. It is a pink blush and not a venous stasis. A direct injury of the iris or a wounded, swelling lens may cause a mild iritis, but no exudate appears in the anterior chamber or pupil. Vitreous opacity, if not of infectious origin, results only if the vitreous body has been directly wounded and it is distinctly localized. When any deviation occurs from this ideal clinical course, we must ascribe it to the entrance and growth of microbes. The difference between an aseptic and a distinctly infected wound is a striking one by the increase and persistence of symptoms and inflammatory lesions. But there are, too, some instances in which the infection never proceeds far and in which the struggle of the tissues with the invading microbes soon ends in victory. These cases present a series of transitions between an aseptic and a distinctly infected course and are sometimes not easily recognizable as infectious complications.

We can distinguish between purulent and plastic inflammation following wounds, although sometimes a combination of the two types is met with.

*Purulent infection* is caused either by the familiar pus-cocci or by some less common pyogenic bacilli; at any rate, by microbes easily identified. It is usually of violent onset and indicated by pain, tenderness, vascularity and edema of the lid. When it begins in a corneal wound, the edges of the latter become infiltrated. Scleral wounds, however, do not show the infection. A purulent iritis leads to an accumulation of yellow pus at the bottom of the anterior chamber. Abscess of the vitreous is suggested by the early appearance of an exudate in the pupillary space. While mostly progressive, still the purulent process may stop at any of these stages and not proceed further, and in such instances recovery is still possible. An extension of the purulent inflammation into the entire choroid, however, precludes recovery of sight. Purulent choroiditis is indicated by the rapid onset of intense inflammatory symptoms with exudate in the pupil and often with pus in the anterior chamber. The inflammatory edema of the upper eyelid and of the conjunctiva of the eyeball is a specially characteristic sign distinguishing purulent from plastic inflammation. In the most intense form of purulent infection—panophthalmitis—the eyeball is protruded by edema of the orbital tissues. In this form spontaneous perforation of the sclera occurs after about a week's intense suffering. Through this perforation or through a surgical incision scant pus escapes. But the escape does not drain the eyeball promptly, as the condition is not one of accumulation of fluid pus but of phlegmonous infiltration of the tissues. Purulent irido-choroiditis without perforation subsides after some weeks, but always leads to moderate shrinkage of the eyeball. Panophthalmitis with perforation leaves a small phthisical stump after a course of about two months. It has been noted that the shrunken orbs, after a purulent process has terminated, usually become quiet and do not threaten the other eye. But during the active stage we can not predict this relatively fortunate result with certainty, at least in the less virulent cases, since moderate purulent inflammation may coexist with plastic irido-cyclitis.

The purulent infection beginning in the cornea can sometimes be checked by prompt galvano-cauterization of the infiltrated edges. Tapping the anterior chamber, preferably with the hot platinum point, favors arrest of the purulent process if it has not yet invaded the choroid. Subconjunctival injections of salt solution (0.6 to 2 per cent.) are praised by many. Schirmer has lately claimed an almost specific influence of mercury in arresting the purulent process if pushed within the first four days. He prefers inunctions of about 4.00 gray ointment twice daily. His records certainly show a series of recoveries which hitherto would have been considered quite exceptional. But in severe purulent infection all means fail. If the symptoms increase steadily we must terminate the suffering by enucleation or evisceration. If nothing is done the long suffering ceases when shrinkage begins and the remaining small stump is usually quiet and of better size than after any operation. But the pain and the possibility—however slight—of sympathetic disease usually urge operative interference.

*Plastic inflammation* following wounds is usually not as acute in its onset as purulent infection. The traumatic irritation does not subside, but gradually increases to a degree not explicable by the mechanical dis-

\* Except the chemical changes due to soluble foreign bodies or a later shrinkage of the injured vitreous leading to detachment of the retina.

turbances and the climax may not be reached until perhaps the eighth day. In the light of our present knowledge we can only regard this inflammation as an infectious complication, but the microbes causing it have never been identified. As a rule, no bacteria, or at least no constant variety, can be demonstrated. Iritis is usually the first manifestation as shown by synechiae, often multiple. In many cases this leads to closure of the pupil in spite of atropin. Extensive redness of the whole visible sclera, decided tenderness in addition to spontaneous pain and punctate deposits on the posterior surface of the cornea prove that the ciliary body has become involved. Extension beyond this area produces diffuse inflammation, but with circumscribed spots of more pronounced infiltration of the choroid coat. Clinically, this choroiditis shows itself by diffuse opacity of the vitreous, provided the pupil is still wide enough to permit a view. As the process continues, a solidifying exudate is formed behind the iris and around the lens, which later on causes the lens to become cataractous. Of ominous significance is a decided softening of the eyeball. While this softening leaves little hope for the future, visible shrinkage of the eye destroys all prospect for recovery. At first the shrinkage may only occur in the region of the wound, causing the scar to appear depressed. Later on the whole eyeball becomes atrophic and indented by the pressure of the recti muscles. At this stage the remnant of light perception is usually lost by detachment of the retina.

The infectious inflammation varies in degree and extent in different instances. It may simply intensify and prolong for a few weeks the original traumatic irritation, or it may proceed to complete ruin of the eye. As long as the pupil can be kept wide and fairly clear on ophthalmoscopic inspection, the prospect for recovery is good. With occluded pupil the prognosis depends largely on the persistence of the disease. If the irritation does not begin to subside within less than a fortnight the prospect is doubtful. If any time after this period the disease seems stationary for a full week without gradual improvement the eye is doomed. Except in the mildest cases, recovery can not be expected in less than six weeks. When the eye is still irritated after the lapse of eight to ten weeks, it is doubtful whether it will ever get quiet. Eyes that have begun to shrink may remain slightly irritable for all time, or are at least subject to occasional spells of active inflammation. In all these instances our anxiety pertains not alone to the injured eye but to the awful possibility of sympathetic disease of the other eye.

#### TREATMENT OF TRAUMATIC INFECTION.

Infection is less likely to occur and less likely to persist when a wound has received proper surgical cleansing and attention from the start. Absolute rest of the eye and of the body should be enforced. The full effect of atropin upon the pupil should be maintained. It is an open question how much can be accomplished by subconjunctival injections of salt solution. I have received the impression that they can hasten recovery when the irido-cyclitis begins to subside, but have never been convinced that they can check the unfavorable progress of the disease. Hot applications seem often of service. The simplest method is to saturate a large handful of absorbent cotton with hot water. In a recent important communication Schirmer has claimed for mercury an almost specific influence upon traumatic irido-cyclitis, provided it is used sufficiently early and energetically. He employs mainly mercurial inunctions, but supple-

ments them with intramuscular injections when urgency seems necessary. In 39 cases of plastic irido-cyclitis he preserved a quiet eyeball in 4 instances and maintained good sights in 23 cases. Such extraordinary results by a competent observer make it obligatory to test his claims in every suitable case. While mercury has been considerably used in European clinics, no one else has hitherto employed it so systematically nor recorded such results. Salicylate of sodium exerts an unmistakable influence upon the infection, provided it is given in sufficiently large doses. Personally, I have learned to depend upon not less than 1.3 to 1.5 grams five or six times per day. In cases of a specially malignant course, however, it can be seen speedily that no treatment is of influence. As soon as the prognosis appears hopeless the eye should be enucleated.

#### SYMPATHETIC EXTENSION TO THE OTHER EYE.

Any eye injury followed by prolonged inflammation involves the possibility of sympathetic danger to the other eye. It is necessary to distinguish clearly between sympathetic irritation and sympathetic inflammation. The former is a neurosis of a non-progressive nature which ceases as soon as the exciting eye is cured or removed. The latter is an inflammation in the second eye of progressive tendency and not influenced directly by the removal of the first affected eye. A moderate degree of sympathetic irritation is often seen as the result of irritative conditions which never lead to actual disease of the second eye, such as corneal ulcers, staphylocoma and glaucoma. The term is, however, used mainly with reference to the annoyance produced in a healthy eye by chronic irido-cyclitis of its mate. The symptoms are sensitiveness to light, watering, fatigue on use and enfeeblement of the accommodation. All the symptoms cease promptly and permanently upon removal of the offending eye. There is no definite relation between sympathetic irritation and inflammation. The former may persist indefinitely without occurrence of the latter, and the latter may begin without preceding irritative symptoms. Still, sympathetic irritation indicates that the injured eye might prove dangerous and should be removed.

Sympathetic inflammation may begin gradually in the form of a mild cyclitis producing slight redness of the eyeball and blurring of sight by the deposition of fine opacities on the rear surface of the cornea. Ophthalmic inspection, if still feasible, often shows at this time inflammation of the optic nerve. In other instances the disease is ushered in from the start as a violent irido-cyclitis with great pain and visible irritation. In either case the fine deposits on the rear surface of the cornea are one of the most constant and characteristic signs. The iritis soon leads to synechiae more numerous than is usually seen in other forms of iritis. It is difficult to keep the pupil wide by atropin. As the disease continues the vitreous becomes cloudy and sight is still further reduced. Unless checked at this stage the inflammation extends into the entire choroid tunic and follows about the same course as described of the traumatic infectious irido-cyclitis of the first eye. The ultimate outcome in malignant instances is closure of the pupil, exudate underneath the iris and around the lens, cataract, shrinkage of the eyeball and detachment of the retina.

In the more fortunate instances the disease may cease after 3 to 6 weeks' duration. As a rule, it lasts many months. After apparent cessation, relapses, often very tedious or even fatal to the eye, are so common that

no patient can be considered safe until he has been free from irritation for at least a year. The longer the duration the poorer the prospect for the preservation of sight. Yet sometimes a moderate result is observed after a course of many months. Formerly 15 per cent. of recoveries with preservation of more or less useful sight was considered the best that could be expected in sympathetic irido-cyclitis. Of late years the use of salicylates has probably reduced the losses to less than 85 per cent., but no large statistics are available.

Sympathetic disease can occur besides in two other forms in which the prognosis is much better than in plastic irido-cyclitis.

The so-called serous form of cyclitis is characterized by pain, tenderness, ciliary injection and the presence of deposits upon the rear surface of the cornea, and negatively by the absence of iritic adhesions and of visible exudate. As long as the disease retains this character complete recovery is possible, even though it may last many weeks. The prognosis is uncertain, however, as this form may at any time change into the more malignant plastic inflammation.

Relatively rare, too, is another type of sympathetic disease, viz., papillo-retinitis. In this form there are no external signs of irritation. The failure of sight is due entirely to the inflammation of the nerve and retina. Every instance of this form in which the exciting eye was removed recovered promptly after the lapse of some days or weeks.

#### ORIGIN OF SYMPATHETIC DISEASE.

The only lesion which can induce sympathetic ophthalmia in the second eye is plastic irido-cyclitis of the first. With rare and almost doubtful exceptions it is an irido-cyclitis following an injury or operation; in other words, an inflammation caused by the entrance of certain parasites through a wound. It is not the injury that threatens sympathy. Aseptic wounds, no matter how destructive, never affect the second eye. Nor is it the presence of a foreign body as such. As long as a foreign body is tolerated without inflammatory reaction the second eye is in no danger. If, however, the typical inflammation reappears in an eye hitherto quiescent, no matter whether it harbors a foreign body or not, sympathetic extension becomes possible. The shortest interval ever recorded between the infection of the first eye and disease of the second is a fortnight. But anything less than three weeks is excessively rare. From the fourth until about the sixth week is probably the period in which extension occurs oftenest. But as long as the first eye remains inflamed the danger of sympathy is present. If the inflammation returns after a period of quiescence, no matter how long, the danger, too, returns. I have seen sympathetic disease started by an injured eye which had been quiet for 40 years. It requires a number of days for the disease to extend from the first to the second eye. Hence, it has happened in a small number of recorded instances, that the inflammation made its appearance in the second eye after a dangerous diseased eye had been removed. The occurrence is undoubtedly very rare. Its probability becomes very much reduced after the lapse of a week. Still, it has been observed even as late as the 18th and the 24th day after enucleation. It is a striking fact that all these instances of affection of the second eye after removal of the first ran a mild course and ended in recovery. There are on record a number of cases of alleged sympathetic disease said to have begun at much later periods than four weeks after removal of the in-

jured eye, but when closely investigated these instances can not be admitted as well-identified examples of sympathetic inflammation. Neither the lesion nor the course of any of the forms of sympathetic ophthalmia are absolutely distinctive of their sympathetic origin. The etiologic diagnosis "sympathetic" must be based upon the presence (or presence within a few weeks) of an eye capable of exciting sympathy and an interval between the disease of the first and of the second eye in accordance with general experience.

Sympathetic ophthalmia is not a frequent occurrence. As far as incomplete statistics show it follows traumatic inflammation in probably much less than 5 per cent. But this applies only to present conditions when the majority of dangerous eyes are removed sooner or later. The disease undoubtedly was much more common one or two generations ago, before preventive enucleation was extensively practiced.

#### PREVENTION AND TREATMENT OF SYMPATHETIC DISEASE.

The practical rules concerning preventive enucleation can be summarized as follows: Enucleation (or evisceration) should be done at once when a penetrating injury has damaged the eyeball beyond hope by crushing, copious hemorrhage into the vitreous, large loss of vitreous with collapse of the eyeball, and especially with dislocation of the lens. When a foreign body has entered the eyeball an effort should be made to save the eye by immediate removal of the body, unless so large that it has disorganized the tissues. If the body can not be extracted, the removal of the eye may be postponed if the body is of iron or steel and can perhaps be reached later, or if small and presumably sterile, like grains of powder or small shot. Chips of glass and bits of rock may also justify a few days' delay with the doubtful hope that they may be tolerated. In all other instances of foreign bodies enucleate at once. When infection follows an injury enucleation need not be considered as long as the inflammation has not extended beyond the iris and as long as a clear ophthalmoscopic view is possible through a wide and unobstructed pupil. As soon as the intensity of the inflammation has led to closure of the pupil or as soon as cyclitis has become evident by deposits on the rear of the cornea, by exudate within the pupil or by diffuse opacity of the vitreous, the danger period has begun. The patient must be warned that the postponement of enucleation beyond the time when the surgeon will demand it means risk to the other eye. It is during the first few weeks of traumatic infection when it is most difficult for the surgeon to decide whether to enucleate or whether to attempt to save the eye, provided the chances are still good for the preservation of sight. However anxious one may be to keep an eye which may ultimately recover with useful sight, it must be remembered that sympathetic disease can be excited by an eye which still has moderate vision. It is only when the pupil is free from exudate and the ophthalmoscope shows a vitreous without diffuse opacity that no fear of sympathy need be entertained. If the inflammation does not subside beyond question after the first week, or if the decline of the symptoms does not continue at such a steady rate that recovery from inflammation is to be expected in about six weeks at the latest, it is dangerous to defer enucleation. An eye which is steadily recovering from the infection may still damage the other, but the probability of such an accident is very small. An eye, however, in which inflammation lingers without change is never worth saving, no matter how little inflamed or how good the remnant of sight.

After apparent recovery of an injured eye it must be determined whether the globe is entirely free from inflammation or not. Lingering disease, not ordinarily noticeable by the patient, is indicated by either tenderness on pressure or ciliary injection or both combined. The ciliary injection may show itself merely by the diffuse engorgement of small veins near the periphery of the white of the eye with relative pallor around the cornea, or it may only amount to a flushed appearance brought on by examining the eye. In either case it indicates the presence of inflammatory foci in the choroid and such an eye may cause trouble if not removed. When a formerly-injured eye becomes inflamed again after a period of quiescence, it is even more likely to cause sympathetic mischief than after the original infection and any extension of the disease beyond the iris should be cut short by enucleation.

When sympathetic inflammation has begun removal of the exciting eye does not affect it to a noticeable extent—at least at the time—except when the disease is limited to a neuro-retinitis. This exceptional type of sympathetic inflammation is invariably cured by removal of the other eye. But the common irido-cyclitis pursues a course apparently uninfluenced and often enough ends in ruin of the eye. Yet a striking observation shows that the continued presence of the offending eye is not without real influence upon sympathetic involvement of the other. Every recorded case of sympathetic outbreak after a preventive enucleation was of a mild type and ended in recovery. Hence the usual plan of enucleating promptly after sympathy has begun is correct. An important exception to this rule must, however, be recognized. An exciting eye with vision or a reasonable prospect of sight should never be removed after sympathetic disease has started, since one can never predict the outcome of sympathetic disease and the injured eye may ultimately prove the better of the two. This has been illustrated a number of times by the patient's refusal to sacrifice the first eye, which in the end turned out to be his salvation from blindness.

The treatment of the sympathizing eye is the same as that of the primary eye. Atropin to the utmost extent, rest and darkness are of prime importance. Local heat always deserves trial. Castor oil is probably not useless. All observers who have used salicylate of sodium in large doses agree as to its pronounced influence. It should be pushed to the limit of tolerance without hesitation. To the salicylate more than to any other measure must be attributed the better results of late years. Mercury by inunction has always been employed, especially in European clinics. Yet it can not be said that there is any positive proof of its benefit in this disease. Schirmer's remarkable success with mercury in the inflammation of the first eye as well as his luck in not meeting a single instance of sympathy in 62 successive traumatic infections, are certainly a strong plea in favor of this agent, although even this can not be considered an absolute proof.

General experience has shown that no operation—iridectomy or removal of cataract—no matter how properly indicated, should be done either in the injured or in the sympathized eye until many months have elapsed after complete recovery from all inflammation. Many an eye with the best prospects for sight has been lost because some operation done too early rekindled the slumbering infection.

In spite of much work by competent authors the parasite of infectious and of sympathetic irido-cyclitis has

not yet been identified. No explanation, however, in any way acceptable, has even been offered except the assumption of a microbic origin. The path along which this pathogenic influence travels from the first eye to the second is likewise not definitely determined. The lymph space between the sheaths of the optic nerve from the eye to the chiasm and vice versa is the route suggested by most experimental and pathologic observation.

#### ACTION OF SILVER NITRATE AND CHROMIC ACID ON CHRONIC GLOSSITIS, UNDER THE INFLUENCE OF THE ELECTRIC CURRENT.

M. L. RAVITCH, A.M., M.D.  
LEXINGTON, KY.

One is surprised at the number of patients who present themselves for treatment of chronic glossitis with negative results. Under the name of chronic glossitis are included leucoma, leucoplakia, glossitis desiccans, ichthyosis, tylosis or eczema, and keratosis. I need not go into the description of the aspects of the different forms of this disease.

Present knowledge of the etiology of chronic glossitis is so imperfect that therapy for any form of this disease has not advanced proportionately with that of other diseases. In view of the fact that even after the removal of the supposed cause the disease does not readily yield to treatment, I make a suggestion of using 15 per cent. solution of nitrate of silver or 5 per cent. solution of chromic acid under the influence of the galvanic current in cases of chronic glossitis. The manner in which I treat my cases is the following: After painting the patient's tongue with a 15 per cent. solution of nitrate of silver or 5 per cent. solution of chromic acid, the patient is told to hold the wet positive sponge electrode in one hand while the negative metal electrode is rubbed over the painted diseased areas for from ten to fifteen minutes; an excess of saliva is produced and it is caught by the patient or operator holding a large piece of absorbent cotton to the mouth.

I use mostly nitrate of silver, though chromic acid has given me satisfaction. The action of these agents on the tissues under the influence of the electric current may be thus explained: Silver nitrate is first separated into ions, the silver cation, Ag, and the nitric acid anion, NO<sub>3</sub>. The silver ion then goes to the negative pole and separates as metallic silver. On the other hand, the nitric acid ion does not separate as such, but decomposes the water present in such a way as to produce nitric acid and oxygen. Therefore, the cauterizing effects of a solution of silver nitrate under the influence of the electric current are due to nitric acid and active oxygen.

In this connection it would be observed, however, that one effect of the current is to cause migrations of the ions in opposite directions, the silver ion toward the negative electrode, the nitric acid ion towards the positive electrode, hence the effects of applying the negative electrode to a surface painted with a solution of silver nitrate, the positive electrode being applied to a different part of the body, is to remove the silver at the negative electrode and drive nitric acid ion deeper and deeper into the tissues where it acts upon the water in the manner above indicated, forming nitric acid and oxygen, hence we would be led to expect better results from the application of silver nitrate in this manner than from the usual method.

In the same way when a surface of the body is painted with chromic acid and the current applied, keeping

the negative electrode on the part painted with chromic acid and the positive on some other part, the chromic acid is resolved into its ions, the hydrogen ion,  $H^+$ , and the negative ion,  $CrO_4^-$ , would at once migrate, the former to the negative, the latter to the positive pole. Then the hydrogen of the chromic acid is removed at the negative pole, whereas the  $CrO_4^-$  ion penetrates deeper and deeper into the tissues. In the tissues it is decomposed by water into oxygen and chromic acid, which again is acted on by the current in the manner already described. At the same time, however, another action is taking place. The chromic acid ion  $CrO_4^-$ , and chromic acid itself, finding themselves in contact with the tissue, rapidly oxidize it with the production of the basic oxide of chromium, which is green in color.

Pain of which most patients are apt to complain is greatly relieved by galvano-chemical applications. The hyperemic condition of the tongue gradually subsides, the tissues become more natural, the patches gradually fade away and the tongue assumes its healthy color. From twenty to thirty applications is all that is needed even in the severest cases. Irritant condiments must be forbidden and the digestion attended to.

A curious fact in cases of chronic glossitis is that women hardly ever suffer from this ailment. In conclusion I desire to express my thanks to Prof. J. Kastle of the State College for assisting me in investigating the chemical action of the above-mentioned metals under the influence of electric current.

The following cases form the basis of my article:

CASE 1.—Mr. W. F., aged 31; has been under treatment for chronic glossitis (psoriatic form) for over 6 years, history of specific nature. Did not yield under any treatment. A 20 per cent. solution of silver nitrate was applied with the aid of the electric current; pain and patches entirely disappeared in twenty sittings.

CASE 2.—Mr. C. P., aged 46; leucoma of the tongue of four years' standing. History non-specific. Discontinuance of smoking and diet did not improve the disease. Fifteen applications of 5 per cent. solution of chromic acid under galvanic current greatly improved the tongue. Patient, deeming himself cured, did not return.

CASE 3.—Mr. G. V., aged 26; eczema of the tongue of two years' standing, non-specific. Ten applications of silver nitrate under electric current were administered. Patient discharged cured.

CASE 4.—Mr. J. R., aged 47, keratitis of the tongue, non specific, pronounced by one doctor to be cancer of the tongue. Complained of pain and itching. Eighteen applications of 20 per cent. silver nitrate solution under electric current were given. Patient discharged cured.

CASE 5.—U. R., aged 32; leucoplakia buccalis, non-specific. Fifteen per cent. solution silver nitrate was applied. After ten sittings, patient did not return, although greatly improved.

## FOREIGN BODY WITHIN THE ORBIT.

ALBERT B. HALE, M.D.

CHICAGO.

On April 9, 1901, Mr. J., a retired business man of 79, while striking a blow with a hammer, felt a stinging pain in his left eye. His daughter could find nothing, but although there was no pain and perhaps only such dimness of vision as would accompany any blow, something about the appearance of the eyeball aroused her suspicions. The writer arrived at the house about one hour after the accident. The patient was calm enough and rather laughed at the need of medical attendance. There was still no pain and practically no redness of con-

junctiva or sclera. On the cornea, two millimeters below the apex, in the lower outer quadrant, was a very small perforation which was no longer patent but had already begun to repair; there was practically no opaque area. The anterior chamber was restored and in it no blood could be detected nor was the fluid cloudy. The iris, however, showed that the penetrating body did not stop at the cornea; corresponding exactly to the corneal wound there was in the iris (lower outer quadrant) a lacerated perforation. The lens showed that the foreign body had not stopped at the iris; a very faintly opaque line could be traced through it. The vitreous was not yet cloudy nor was there any noticeable path of a foreign body through it and the fundus was quite clear with every detail of the posterior half distinct and nothing abnormal discoverable.

Atropin was immediately used and within four hours a maximum effect was produced. The perforation through the iris was now nearly obscured by the contracted membrane and the lens showed more plainly the path of the foreign body. In fact, cataractous changes had already begun, so that the lens was now noticeably opaque and consequently fogged materially the details of the fundus. By nine o'clock the next morning the lens was so opaque, especially in the lower, nasal quadrant, that effort to study the fundus was abandoned. An x-ray photograph was then taken with positive results. The foreign body was demonstrated, but although an effort was made to locate it by different photographs in different planes (Sweet's method<sup>1</sup>) no exact success was obtained.

Twenty-four hours after the injury there was only such slight pain as would be ascribed to excessive manipulation. The hammer had been carefully examined as this was the only substance from which a foreign body could have sprung. Wood, on which he had been hammering, could not have produced so small an injury and, although the head of the tool was so rough as to prevent certainty of finding a bit missing, yet practically there was no doubt that the foreign body was a piece of steel. Had an Asmus sideroscope<sup>2</sup> been accessible it would have been used. Twenty-four hours after the x-ray there was slight pain, some redness and scarcely noticeable swelling. Tension was not increased.

The patient was a man of wide experience and of a thorough acquaintance with physicians and surgeons. He invited confidence and his mind was calm enough to consult on his own case with philosophy and judgment. It must be here stated that his health was not of the best. He had had two attacks of pneumonia wherein hope of recovery had been very small; his heart had thereby suffered, so that his attending physicians had warned him that he might at any moment have an apoplectic stroke or an embolism. Life, therefore, although dear to him, was doubly precious if the few remaining months or years could be enjoyed in comfort, with no pain beyond that to which he was accustomed and with no fear of impending operations, either one to remove threatening disaster of sympathetic ophthalmia, or to repair the result necessitated by intra-ocular investigation of the injury already done. Moreover, he had an acquaintance who had been injured in much the same way, but who, after patiently submitting to a magnet operation and life in a dark room for six months, had finally been obliged to lose his injured eye in order to retain its fellow.

The surgeon's attitude to such an accident was explained to the patient. 1. The eye could be

let alone, trusting that nature would heal the wound and allow the foreign body to lie quiescent in its bed, somewhere in the choroid (presumably near the ciliary body); that soon, however, the lens would have to be removed as it was already quite opaque and would render the eye useless until extracted; that after extraction this eye would never be so good as its fellow, and would always have to wear a glass, but would see and be a useful organ, although there would always be danger from the foreign body. 2. To investigate at once with a magnet, to extract the steel, to allow the eye to become quiescent and then to proceed with the extraction of the cataract. 3. To enucleate at once, even before inflammation showed itself; by which treatment he would lose an eye, but would, in all human probability, escape the danger of sympathetic ophthalmia, would be detained but a few days in hospital, have only a few weeks of peaceful convalescence, and within a reasonable time could wear an artificial eye and, excepting for this change, could return to his avocations with as easy a mind and body as he had had before. The patient chose the last method of treatment, which was according to the writer's advice. Sixty hours after the eye was injured it was enucleated, ether being used as anesthetic, and the encouraging prediction was verified, for he remained only five days in hospital, there was absolutely no reaction either local or general, he escaped all pain, and five weeks after the injury he was wearing a glass eye and reading his newspaper as if nothing had happened.

After his return home he suffered a very sudden but mild attack of aphasia and partial paralysis of the arm and leg, due to a small embolism in the left brain, but from this he recovered quickly and completely.

The enucleated eye was immediately hardened in one per cent. formalin solution and when ready was prepared and mounted according to the method of Priestley Smith.<sup>3</sup> The accompanying cuts show nicely the injury to the iris and lens and the path of the foreign body to its seat in the choroid near the ciliary body.

There is due some explanation of the patient's wishes for preferring this third method of treatment and of the surgeon's reason for advising it. On personal grounds he argued that he had only a slight hold on life, and his remaining days he hoped to pass in peace and comfort; he did not fear death, as he often said, but he dreaded above all things the invalidism of the old, which might be a part of the magnet operation, of the subsequent reaction and of the cataract operation, necessary to restore to the eye its usefulness; hanging constantly over him there would be the haunting fear that some sudden change in the eye might precipitate an inflammation, in itself dangerous to both eyes and demanding the enucleation to avoid which had been the purpose of all the treatment. Undoubtedly this feeling was intensified by his knowledge of the experience of that friend who had suffered a similar injury, in whose case the magnet operation had been performed *secundum artem*, but after six months of dark room, pain and idleness, he lost the eye after all. He ended with the remark that one good eye was worth two bad ones in danger, so far as his own future was concerned.

To examine the matter scientifically is to cover the history of modern ophthalmology. The result of the third plan of treatment suggested is illustrated by the history of this case; let us study the first plan, to see how it might have ended. Undoubtedly earlier surgeons were aware of the danger after penetrating wounds

of the eyeball and took steps to give immediate relief, but Mackenzie's investigation of the relation between such injuries to one eye and subsequent inflammation and loss of sight in the other (1840) finally established the clinical fact that protection was most surely obtained only by an early enucleation of the injured member; although even in the 1855 edition of his work enucleation is not systematically advocated. The prevailing theory to explain the migration from one eye to the other was until recently that of a ciliary neuritis, which traveled by some undemonstrable means across the brain. This theory is not yet abandoned by all, even of the keenest students, but owing to the growth of bacteriologic enthusiasm, most investigators, headed by Deutschmann, would seek to trace the etiology of sympathetic ophthalmia directly to the poison of microorganisms (or their toxins) along the optic nerve sheath and the chiasm to the optic nerve of the sympathizing eye. The investigations of Alt, Gifford and others support this theory, so that Schirmer<sup>4</sup> assumes the theory as nearly proven. I do not care to discuss the subject here, but use the point to emphasize the statement that with the growth of scientific surgery there has developed in ophthalmology a dread of loss of the second eye after a penetrating wound, especially at the ciliary region—the so-called dangerous zone—of the first eye, and the tendency has thereby been strengthened to enucleate early if the eye has been seriously damaged, even at the risk of seeming haste, because of unwillingness to wait and hope for the tendency of nature to repair the injury within the confines of its own orbit. It took many years of study, however, to reach this conclusion, and the disasters following a waiting policy can be found in most text-books of eye diseases prior to 1860. Granted that there can be cited instances of retained foreign body that did no damage, there remains the equally acknowledged fact that the danger from such retained substances seems not to find a limitation in time, and that, therefore, sympathetic inflammation may even years after work destruction. *Laissez faire* means courting disaster; immediate operation means relief, escape from disaster with the loss of an eye.

Hence enucleation was certainly the indication until the introduction of the electro-magnet into eye surgery. Of course, it had instinctively occurred to man to remove iron by a magnet, but an ordinarily magnetized metal was not strong enough to influence small particles through living tissue and not till the growth of the electro-magnet and its perfect adoption in a sterilizable form did it become of practical service in surgery. The world will never know what a debt of gratitude is due Hirschberg for his enthusiasm for the electro-magnet. As early as 1879 he published his first case of magnet operation in which a successful result was obtained. In 1896 he could rejoice<sup>5</sup> that there had been one hundred eyes saved by this modern means, and he compares experiences before and after the magnet epoch. During ten earlier years, for instance, there was not one good result in treatment of retained penetrating (metallic) foreign bodies. In 10 subsequent years 13 cases showed 7 good magnet results with only 6 losses. Again, in Zürich, 24 eyes were lost before the magnet, while afterward, although 24 were lost, there were meanwhile 11 saved. In 43 cases of magnet operation (Haab), there were only 5 lost by suppuration, whereas hitherto the proportion of such losses was appalling. In 1895 there was only one failure to find iron out of 15 cases.

Hirschberg is, of course, a strenuous advocate<sup>6</sup> of his

small electro-magnet; Haab, on the other hand, champions the large magnet,<sup>7</sup> though acknowledging that both should be placed side by side in the operating room.<sup>8</sup> Undoubtedly this modern method is a step in advance, and will be made still further serviceable as mechanical genius brings aid to surgery; already the Asmus sideroscope<sup>2</sup> is added to this equipment and contributes to our securing favorable results. Briefly stated, this instrument is a delicately adjusted magnetic needle which deviates from its position of rest when it is approached to sympathetic metal. For instance, Goldzieher,<sup>9</sup> when other means had failed, discovered by the sideroscope alone the location of the metal in a recent injury and successfully extracted it, leaving a healthy eye with one-half normal vision.

Such a case as this shows us, however, that there is a dark side which has not been studied with the care demanded by the impartial critic. No one can deny that the vision of an eye is its vital function; destroy this, and the eye, though normal to look at, becomes useless to its possessor. Mar its beauty, as is almost always done by a penetrating foreign body, and it is often not so good as a glass substitute, but when sympathetic ophthalmia may still be threatened by a useless globe, better out with it forever. To save the vision, then, is the object of all our endeavor and, until the magnet operation can give more assurance that it will preserve useful vision, let us acknowledge that enucleation still has its place as an operation of choice. Take Gold-

zieher's case above, in which vision was one-half—splendid, of course, but the eye is no longer perfect. Another case<sup>10</sup> may be cited where the magnet was used with success 24 days after the injury: here success was claimed, but poor vision is acknowledged by the operator. Coppez and Gunzberg<sup>11</sup> report 41 cases with 8 of the foreign bodies located in the anterior, and 33 in the posterior half of globe. Of 15 magnet operations attempted the results were 7 enucleations (one being after operation where sympathetic inflammation had begun), 8 eyes saved; of which one had vision of 2/3, two had light perception and five mere retention of the globe. Kibbe<sup>12</sup> is an enthusiast for the magnet operation and yet he concludes his report as follows: "The precise location of a foreign body within the eye, not directly visible, is impossible by any known method." Of his 11 cases (Haab's magnet) 2 recovered, but the vision is not given; one could count fingers only; 1 had vision of 20/40 with a lens; one of 20/200; one of 20/70; one was enucleated afterward; one had a capsular opacity with hope of subsequent improvement, and one was entirely blind. The other two escaped observation. Velez<sup>13</sup> reports as follows: One case where the piece of iron lodged in the anterior chamber, in which the Hirschberg magnet was used, resulted in a vision of 20/20; another, in the vitreous, vision of 1/10; a third, where one piece of iron was removed but a second piece left (neither x-ray nor sideroscope used), subsequent loss of the eyeball; another, where the lens was at the same time removed for the traumatic cataract, vision of 1/10.

Sweet and Hansell<sup>14</sup> report a case in a fourteen-year-old boy, with successful extraction and subsidence of sympathetic irritation, four months after an injury, with retention of globe and some vision, but where vision might have been saved had proper diagnosis and treatment been begun at once. Mendel<sup>15</sup> reports a case in which a piece of iron, which had lain dormant four weeks in the retina, was extracted, leaving normal vision and nearly normal field. Barkan<sup>16</sup> reports 11 cases, in which there were 3 enucleations, 8 recoveries, of which 4 had good vision, fingers at 5 feet, 20/70, 15/20, Haab's magnet being used. Sweet<sup>17</sup> has collected from American literature 61 cases of similar injuries. In 16 of these, where no attempt at extraction was made, the injury resulted in enucleation 9 times; 4 patients refused interference with 3 disappeared from observation. In 45 cases, extraction by magnet was attempted. There were 7 failures, resulting in 5 enucleations, 2 escaping observation. In 38 cases the following were the usual conditions: 10 had vision of 6/18 or better (22.2 per cent.); 5 had vision of 6/60 or better (11.1 per cent.); 8 had traumatic cataract (17.7 per cent.); 8 had light projection (17.7 per cent.); 7 had atrophy of the bulb (15.5 per cent.).

Certainly these are grand results. Eyes are undoubtedly saved and the possibilities for the future are undoubtedly full of promise, but the grim fact remains that in many cases the final signature was poor vision or enucleation. From a series, no matter how elaborate, one can not draw conclusions by averages; one must study the individual and the accident befalling him. In the writer's case above, peace of mind and days of life far outweighed the ambition for scientific progress. In a younger man, with his future before him, to whom an eye disabled to half its value, deprived of its lens and condemned, if assisting its fellow, to do so only by an eyeglass, but an eye in which the field of vision was still retained to aid in enlarging the outlook on the world—in him try the Roentgen ray, try the sideroscope, try the Hirschberg or Haab magnet and thank God for them all. If enucleation must finally be done it has cost only a few months of waiting and has meanwhile warded off the blackness of despair. But to an old man, to whom every day means a closer approach to the grave, the advice would be—unless the diagnosis and attack be sure—do not wait; beware of effort that may prove futile; cling to the certainty and be thankful that we know where and even at what cost this is to be found.

So much we have gained, then: eyes that before would surely have been lost, may be saved. True conservatism consists, however, in establishing for the patient's future the greatest comfort within our power.

### SOME ATYPICAL FORMS OF DISEASE.\*

JAMES L. TAYLOR, A.M., M.D.

WHEELERSEBURG, OHIO.

One of the fields of largest promise to the medical investigator of the future is that which holds the secrets of attenuation and malignancy of germs which cause infectious diseases. While laboratory processes have shed some light on this interesting subject, the fact remains that diseases spring up, prevail for a time in mild, severe or malignant form, and finally disappear according to laws that, for all practical sanitary purposes, are yet unknown. On the first appearance of a disease, no one can tell whether it will prove to be sporadic or epidemic, benign or virulent, of widely extended or only local prevalence. Extreme virulence may stamp a brief sporadic outbreak, while a very benign infection may be widespread and of long duration. Or—as happens more frequently—these conditions may be exactly reversed. Nevertheless, the term “epidemic constitution” so long used by the older writers to explain these conditions, or rather to veil their ignorance of them, is no longer employed. We now speak of germ virulence or attenuation. But our actual knowledge, as to why the germs are virulent in one outbreak and benign in another, or why a change of type often takes place during the same epidemic, is about as meager as before.

A practical result of this varying germ activity is a tendency to confusion in our accepted nosology and in the diagnostic recognition of different forms of disease having the same underlying cause. A most remarkable example of this confusion has lately been seen in the smallpox visitation so widely prevalent in this country. There being no established germ criterion in this disease, and therefore no unerring means of diagnosis, it has been stoutly maintained in many quarters—and by very competent medical men—that the disease in question could not be genuine smallpox. Its behavior certainly has been exceptional. No one in this generation having seen any similar outbreaks, there seemed to be valid grounds for questioning the real nature of this easily managed and in most cases harmless affection. It has been so unlike the ultra-contagious, virulent scourge of which we have all read so much and of which many of the older men have seen so much that, judged by symptoms and results, those who denied the identity of this widespread epidemic with the typical form generally assumed, have apparently had substantial reasons for their opinions.

So distinguished an authority as Dr. J. Nevins Hyde,<sup>1</sup> while maintaining that the disease is genuine smallpox, offers as an explanation of its mildness the theory that vaccination and the inherited immunity conferred by ancestral vaccinations have developed a resistance to germ infection and shorn it of its ancient malignity. As a theory this view is certainly pleasing, since it implies that by continued vaccination, in the process of time the human family may become practically immune. Unfortunately, this view lacks the sanction of both history and analogy. If it were true, we should find no epidemics similar to our own in former times,

but would witness a gradual subsidence in the severity of smallpox down to the present time. This is not the case. Long before the discovery of vaccination—to quote from Trousseau—the writings of Sydenham, Van Swieten and Borsieri described “anomalous epidemics of smallpox presenting all the characteristics of the modified smallpox of the present day.” Curschmann says: “Smallpox in frequency and intensity exhibits the greatest variation in individual endemics and epidemics.” *Per contra*, so recently as 1870-71, in spite of the protective influence of vaccination, “the European epidemic carried off from 18 to 25 per cent. and even more of all who were attacked.” This seems conclusive that we have been witnessing a phase of the disease altogether similar to what has been seen in the past and that its varying types have not undergone a permanent change.

In this particular, smallpox corresponds by analogy, with other diseases. Consider the plague—a disease of most pronounced physical symptoms. Before the discovery of the plague bacillus the literature was filled with descriptions of *pestis major* and *pestis minor*, and discussions were keen as to whether they were the same or different diseases. In 1564, while the epidemic in London carried off 1000 victims a week, the disease was at the same time an everyday occurrence in Paris, and so mild that many people were more afraid of a headache.<sup>2</sup> The one form depopulated whole villages and often seemed to poison its victims to death in a few hours. The other was less to be dreaded than an ague. But to-day all dispute as to the identity of the germ causing the two forms of the disease has ceased.

Every experienced medical man has seen diphtheria and scarlatina behave in the same way. In 1888 I saw scores of children, in fact, nearly all the children in my territory, go through an epidemic of scarlatina so mild in form that most of them continued to attend school. Two or three cases only developed sufficient severity—angina, palmar and plantar desquamation, nephritis, hematuria and dropsy—to emphasize the true character of the disease. The laity, however, named it “the rash,” and when I talked to them about scarlet fever, they were incredulous, and wondered why the doctor should take “the rash” so seriously.

Investigation during the last few years has also established the fact that typhoid infection is subject to greater irregularities and departures from the hitherto accepted types than any of the infectious diseases. The recent volume of Johns Hopkins Reports<sup>3</sup>—a veritable mine of wealth for literature and original research on this subject—is authority without further reference for much that is herein adduced. The discoveries of the pathologist and bacteriologist have wholly revolutionized former conceptions of this disease. The point of view now occupied regarding its origin, dissemination, mode of infection, pathological lesions and behavior within the body presents a new revelation, and much that was considered authoritative, well-founded knowledge, twenty years ago is now obsolete. Then typhoid fever was an intestinal disease pure and simple—a primary dothienenteria. The furuncular eruption on the intestine—at some stage of the disease—was held to be pathognomonic. Now, according to Dr. Camac, the liver is believed to be the primary center of infection. High authorities “regard the gall-bladder as one of the surest places to obtain a pure culture of Eberth’s bacillus.” To what extent the liver may have bactericidal functions is not yet determined, but it seems to be well

\* Read before the Central Tri-State Medical Society, Ashland, Ky.

established that pathologic lesions due to the specific organism may appear there in profusion, as well as in the ducts and gall-bladder, without any visible evidence of coincident intestinal infection. Instead of being confined to the intestinal canal, Flexner says the bacilli may be found not only in the liver and bile but also in the lymphatic glands, the kidneys, lungs and circulating blood. They are even observed in the substance of the central nervous system, in the meninges, the bone marrow, and various lesions of the cutaneous system. In any of the above conditions the usual intestinal lesions may not exist. A pneumonia, a hepatic abscess or a meningitis, caused in either case by the bacillus typhosus, may carry off a patient without a particle of intestinal involvement. Flexner also cites the remarkable experience of Chiari and Kraus who, "in 19 autopsies of typhoid fever, found seven instances in which the anatomical lesions of the disease were wanting. These cases, though negative from the postmortem point of view, had all given positive serum reactions." Such cases, as well as those in which the spleen alone is the suffering organ, indicate a liability to systemic infection through the blood current—a true typhoid septicemia. If typhoid may go on to a fatal termination without any visible anatomical lesions, much more may lighter forms of infection exist without definite localization. Hence, in the light of modern research, he must be a bold man who would deny a typhoid origin to almost any obscure febrile affection of an obstinate nature.

The theory long held which attributed the origin of typhoid infection to a contaminated water supply has also undergone some modifications. Other sources of infection are now recognized as of equal danger with water reeking with the products of cesspool cultures. After the convincing experiments which proved that the common fly may be the carrier of cholera, the inference was easy that flies might also disseminate typhoid poison. Accordingly Celli (to quote from Nuttall) observed that flies fed with pure typhoid cultures voided virulent bacilli, and that animals inoculated with these culture flies were likewise infected, "proving that the bacilli which passed through flies were virulent." Veeder once observed a commode emptied of typhoid dejections, placed, without being disinfected, near a pitcher of milk. Flies collected on both vessels and could readily pass from one to the other. Veeder asks: "Is it strange that there were numerous cases of the disease in that house and others in the house next to it?"

The course of a typhoid outbreak in my own practice in the year 1899 tends to confirm this view of typhoid dissemination. The year before, a girl in a family in the country, who had waited on a sister with fever in another neighborhood, came home with the disease and died. No more cases of it occurred that year in this locality. The next year in August the mother had an obscure ailment lasting several weeks, apparently hepatic in character, from which she recovered. In September five of the children sickened at the same time with what proved to be unusually severe typhoid. At the same time four other families along the road leading to the railway station, living on consecutive farms, also developed the same type of disease in one or more cases. Further on towards the station along the same road, still other families developed the disease simultaneously in the territory of neighboring doctors. The peculiar feature of this epidemic was that it appeared about the same time in all the stricken families, and

only along this road, a distance of nearly three miles. It seemed that the first family with the case in August, or possibly that of the previous year, must have been the focus of dissemination. The course of the road in this uneven country in no way coincided with the direction of surface drainage. The water supply as a primary source of infection could not be considered. At the time it appeared that the dust was the most likely vehicle for its diffusion—the prevailing winds being in the direction of the road leading to the station. Since the study of Germano, however, who found that typhoid germs do not resist drying and are therefore not liable to be scattered in this way, it seems more probable that flies, laden with the germs, followed the teams towards the station in the direction of the prevailing winds and infected the dwellings by the way. When we reflect that the larvæ of flies are hatched in manure heaps and mature there, it is not surprising that they should have access to typhoid excreta in their breeding places, and be able to infect the food and water supply of adjacent dwellings. Knowing this fact, the origin of many obscure outbreaks of the disease is the more easily explained.

Bearing on the subject of obscure disease types, the recent study of so-called typhomalarial fever made by Dr. I. P. Lyon is also of great value. It will be remembered that the term typhomalaria was added to our disease nomenclature by Dr. Woodward during the Civil war. Following this distinction, about 50,000 cases of this disease were reported among the troops with a fatality of only 8 per cent., while 75,000 of typhoid were recorded with a mortality of 35 per cent. The fatality of typhoid was therefore more than four times as great as typhomalaria. Ever since then it has been the rule with many physicians, supported by many medical writers of distinction, to designate mild, indefinite ailments as malarial, and those of a somewhat graver type typhomalarial.

All this refinement in diagnosis, however, vanishes before the searchlight of the microscope, assisted by laboratory methods. A coincident typhoid and malarial infection is now shown to be a rare occurrence. Going through the literature, Lyon was able to collate only 30 undoubted cases, and these were mostly cases of pre-existing malarial infection. He states that "Thayer, in Osler's clinic at Johns Hopkins Hospital, has studied hundreds of cases of malarial fever and of typhoid fever, from the neighboring Chesapeake Bay region and from the Southern States, but has never seen the type of fever described in the South as typhomalarial, and has observed only two cases of true combined typhoid and malarial infection. It seems probable that future investigations will show typhomalaria to be most often a mild form of simple typhoid fever."

So far from being a mild affection, the mixed typhoid and malarial disease presents a high rate of mortality, eleven of Lyon's thirty cases being fatal. This is a mortality rate of over 36 per cent., or five times as great as the mortality from typhoid among our troops in the late Spanish war. This also agrees with the views of French surgeons who describe a true coincident typhoid and malarial infection in Northern Africa and Madagascar as a disease of great severity, attended by a higher rate of mortality than typhoid alone. There now seems no doubt that the term typhomalaria originated in an erroneous conception and that systematic writers on medicine will cease to recognize it hereafter in their nosology.

Viewed in the light of the foregoing facts, what shall be said of that mild endemic disease which has prevailed so extensively throughout the Ohio valley during the past season? Such cases of this continued fever as have come under my own observation could usually be traced to an origin at some point where the Ohio River furnished the water supply. According to the vital statistics of the late census report showing the comparative death rate from infectious diseases of the eleven largest cities in this country, Pittsburg heads the list in the proportion of deaths due to typhoid fever. It is located at the junction of two small rivers which receive the sewage of many towns above and the drainage of a wide expanse of populous territory. It is a great manufacturing city and all the offal of its numerous factories is poured, along with what comes from above, into the Ohio. The towns and cities which line the river below, all drain their accumulated filth and disease germs into the already contaminated current. Should it cause surprise then that the Ohio valley, most of whose towns draw their water supply from this great sewer of five states, usually without adequate filtration, has become the endemic home of typhoid fever? The only strange thing about it is that the disease should be so mild, so atypical in many localities, as to cause uncertainty as to its true nature. In my own territory enough of these cases responded to the Widal test to stamp the disease as genuine typhoid. Neither malaria nor influenza would explain the symptoms and quinia failed to abridge the fever.

Now that we have more accurate means of diagnosis at command, the word typical acquires a new significance. The mild forms which have hitherto been elusive, become just as typical of some epidemics as those less common forms attended with great fatality. The point of view has simply changed, and our conceptions of disease—of typhoid as well as other infections—are correspondingly widened.

### A CASE IN WHICH A LARGE BONE CAVITY WAS HEALED BY MEANS OF THIERSCH GRAFTS.

JOHN PRENTISS LORD, M.D.

Professor of Surgery, Creighton Medical College; Attending Surgeon, St. Joseph Hospital; Consulting Surgeon, South Omaha Hospital.

OMAHA, NEB.

Frank Mocha, a farmer aged 60, referred by Dr. Gilmore, was admitted to St. Joseph Hospital, Oct. 21, 1901. The patient had an acute suppurative osteomyelitis of the upper half of the left tibia, which was engrafted upon a chronic inflammation of the same character, which had been of two years' standing. He had the same trouble, in the same place, when six years of age. He was operated on the day after admission, and a very putrid suppurating focus was removed, which included the medulla and cancella of the greatly enlarged upper half of the bone. The erosion extended to the cartilages forming the knee joint. The cavernous portion of the excavation was large and about four cm. deep and three cm. wide. It was filled with pure carbolic acid, which was allowed to remain for about one minute; then the cavity was flushed out and filled with alcohol, as recommended by Powell. It was then well dusted with iodoform and partially packed with iodoform gauze; about an ounce of boric acid being incorporated

with the gauze, which filled the cavity. After applying a copious dressing, the constrictor was removed and the limb held upright to limit hemorrhage. An elevated position of the limb was maintained in bed for a time, for the same reason. The outer dressing was renewed on the third day. The wound was repacked on the tenth day and at the same intervals for the whole of the treatment, during which there was no suppuration. Nov. 29, 1901, Thiersch grafts were placed throughout the open portion. The result was perfect. Jan. 6, 1902, the cavernous portion was two and one-half cm. wide and three and one-half cm. deep, but it received grafts with equal success. The grafts were placed upon the wetted outer surface of the limb and slid into the cavity by teasing. They were secured by pledgets of cotton wrung from normal saline solution packed into the cavity, which, when half full, was partially filled with boric acid and the remaining portion packed with gauze. The

Bone cavity healed by means of Thiersch grafts.

dressing remained undisturbed for four days, except for some wettings, which it received on two occasions. It was afterward dressed with a mixture consisting of balsam of Peru one part, castor oil seven parts. Epidermization was complete from the first and the patient was discharged cured Jan. 13, 1902.

Trough-like defects in the shafts of bones have been grafted by the author and plastic operations done for the purpose of limiting bone defects and hastening healing, as described in surgeries; yet to graft a large hollow bone defect, as in this case, is the first experience of the writer and he is not aware that it has been done by others. The happy result justifies the belief that a good service has been rendered this patient, who valued time and early cure more than cosmetic results. To have undertaken to fill this large bone defect by the growth of granulations would have required months, with possible failure

in the end to secure complete closure. A sinus with an unhealthy discharge may be inferred to be prone to cancerous development. While the grafted surface might not withstand much traumatism, were it exposed, it is now sound and is so protected as to be little liable to mishap. To have undertaken to fill the cavity by decalcified bone chips or sponge, would probably have resulted in failure. While this large defect remained aseptic under the treatment instituted, the large quantity of bone chips and blood clots necessary, would doubtless have been too favorable a medium for lurking germs.

When this case was exhibited, the question arose as to the strength of the bone. The prolonged osteomyelitis had so thickened the compact layer as to render it sufficiently strong. But the large surface underlying the exposed semilunar cartilages (the entire cancella having been removed from the upper half of the bone), indicated that there would be a point of weakness, but later granulations so limited this area as to leave no room for apprehension. A recent letter states that the cavity has much reduced since the patient has returned to his home. The photograph I present with the article does not do justice to the size of the cavity, which is fully three cm. deep.

#### THE VALUE OF STATE CONTROL AND VACCINATION IN THE MANAGEMENT OF SMALLPOX.\*

J. N. McCORMACK, M.D., LL.D.

SECRETARY OF THE STATE BOARD OF HEALTH OF KENTUCKY.  
BOWLING GREEN, KY.

Vaccination became so popular and universal in all civilized countries in the decades following its introduction that the horrors of smallpox almost faded from the memory of men, and medical writers and teachers habitually wrote and spoke of it as possessing only an historic interest. It is probable that in this age vaccination became so general that more or less inherited immunity existed, as a rule, even where the individual himself had not been subjected to the operation. Then came the reaction against it, and an exaggeration and misrepresentation of the accidents and evils incident to any like remedy used by the laity, as well as by many careless medical men, who had no conception of the value of cleanliness, which philosophic minds should have anticipated. In this the anti-vaccinationist had his day, alongside of him who doubted if Shakespeare wrote his own plays, and the other countless freaks, literary and vulgar, whose only hope of notoriety has been the claim, usually a pretense, of being iconoclasts.

The present epidemic in this country began from cases brought from Honduras to Mobile in the spring of 1897. The early cases were overlooked or neglected, owing largely to the mildness of the disease, which has been characteristic of the entire epidemic. This is probably due in part to the attenuation of the contagium by long prevalence in the tropics, and possibly to some extent to the partial racial immunity before referred to, inherited from generations of vaccinated ancestry, especially in the colored race from the rigid enforcement of vaccination during slavery, and the children of parents recently from Europe. Another reason that caused it to be overlooked was that it was confined strictly to the colored race at the outset. The disease soon reached the mining regions of Alabama and Tennessee, where it rapidly assumed the proportions of an epidemic.

The first Kentucky case came to Middlesboro from Tennessee early in December of that year, and was not recognized as smallpox until many exposures had occurred and a serious epidemic was in full blast. A little later the disease broke out at Jellico, a state-line mining town, and two months later a negro who had contracted the disease at Knoxville came down with it at Richmond. Before a diagnosis was made and the cases reported to the health authorities, another serious epidemic was in full sway. Although the features of these early cases were well marked, and the true nature of the disease was appreciated by the better class of the profession as a rule, ignorant and designing persons spread the report that it was "elephant itch," "Cuban itch," or "African itch," all of which were smallpox in the negro vernacular, names which have persistently clung to the disease in this and other states, much to the confusion of the popular mind. By the rigid application of the usual methods, isolation and enforced vaccination, the disease was stamped out in all of these places, but in a few weeks was imported into other counties and stamped out, and we have moved on in this endless circle in Kentucky for now more than four years. Had the methods of other states been as effective as ours we would never have had smallpox to begin with, or at the worst our trouble would have ended with the eradication of the disease at the places first mentioned. On the other hand, had all of our people been vaccinated at the outset, as the law plainly required, we would never have had a case—unless an imported one—followed by no spread of the disease.

Our official figures show, however, greatly to the discredit of the state, as well as to the medical profession, in my opinion, that only about 15 per cent. of our population was protected by vaccination when the epidemic began, and this chiefly in the cities and towns. In the country districts, practically all were unvaccinated, and if the first case was not recognized and isolated an epidemic was the inevitable result. If the first case was a negro he spread it among his own people, as a rule, and if a white person he gave it to his friends and color, but if its extension was not soon restricted by official action it spared neither race. In the light of an experience with thousands of cases coming under my observation it has shown no preference for the negro race in this climate.

It is doubtful if better opportunity has ever offered for fully and fairly testing the value of official control, in which vaccination is included, in the management of smallpox than during the almost constant prevalence of the disease in some portions of this state in the last four years, or if the history of so many separate outbreaks in country districts has ever been more carefully observed or more faithfully recorded and reported. In that time there have been 405 distinct outbreaks in 112 of our 119 counties, with a total of 11,700 cases and 191 deaths.

In probably a majority of these instances the initial case was an importation from some other state, and often, especially in the country districts, many cases or exposures had occurred before the character of the disease was recognized, or the local board of health had any knowledge of the facts. This was due partly to the mildness of, and low rate of mortality from, the disease, and still more to the fact that we had been so long exempt from smallpox in this country that a generation of doctors had come on which had little theoretical and no practical knowledge of it. As we have efficient

\* Read before the Kentucky State Medical Society, at Paducah, May 7, 1902.

boards in nearly every county and municipality in Kentucky, active measures were adopted to bring the disease under control as soon as it was reported, and these efforts were uniformly successful in the end, although, especially in the earlier years, the work was often hampered, and the difficulties greatly increased, by ignorant fiscal officials who refused or delayed the appropriations necessary for feeding, housing and nursing the indigent sick, and using this pretense of economy as a vote-catching device for reelection to the office then held, or some higher one. This tendency was nipped in the bud by the prompt and unsparing exercise of the power of the State Board of Health to put the town or county in rigid quarantine until such time as proper action was taken by the officials to protect their own people and the balance of the state. To accomplish this seldom required more than two or three days, and soon the intimation that it would be done was all that was necessary.

The literature of smallpox, as contained in the textbooks, is largely based upon observations made in cities, camps, prisons and other crowded conditions, where the opportunities for contagion were so abundant as to constantly render confusion possible as to the results. In our epidemic a large per cent. of the outbreaks occurred in more or less sparsely settled country districts, where each case could usually be traced to its origin and date of exposure, thus affording special chances for studying the natural history of the disease. As a result of these observations the writer has arrived at some conclusions which, if true, and utilized, are of the utmost importance to health officers and physicians in the practical management of smallpox. One of these is that the disease is slightly if at all contagious until the beginning of the pustular stage, which sets in nearly always about the close of the fifth day of the eruption. If a patient with smallpox can be taken from the house, or the other inmates removed, by this time the danger to such persons is scarcely worth considering. If the other members of the family can be thoroughly vaccinated at enough points to make the result certain within forty-eight hours after the beginning of the pustular stage of the first case they will be almost certainly saved an attack. If seen after later exposure than this it is safer to practice inoculation, which I have frequently done, although it is in violation of an almost obsolete statute. I have taken children from the bed and even from the breast of a mother with confluent smallpox up to the sixth day of the eruption, over and over again, and saved them from the disease. In this connection I would like to insist that no person should ever be quarantined in a house with smallpox patients unless they have been previously vaccinated with fresh virus at not less than three places. A violation of this plain and humane rule is the most frequent fault in the management of our physicians and officials, in both town and country districts.

A few words in regard to vaccination and the selection of vaccine virus will conclude this paper. Less would be said upon this branch of the subject if the writer was not convinced that physicians are responsible for much of the lax notions and carelessness which obtains in regard to the importance of universal vaccination. The family physician has it is his power to enlighten nearly every person in this country upon this subject, and he alone can do it in a way that will be heeded.

I would urge that vaccination is the most important operation that most people ever have done, and that if imperfectly done it can only give rise to a false sense of

security. If properly done it is usually a perfect protection against smallpox for a lifetime, and is devoid of danger. Varioloid occurs in persons only partly protected by vaccination. The operation should always be done by a competent physician, with strict aseptic precautions, and the person should be seen from time to time until it can be known that a perfect result has been secured. The virus should be introduced in not less than three points on the arm, about an inch and a half apart, only the scarfskin should be scraped off without drawing blood, and the surfaces should be allowed to dry thoroughly before the sleeve is put down. Protectors and dressings are unnecessary if the abraded surfaces are dried well, and in my experience do more harm than good. Directions should always be given to avoid injuring the parts, especially in changing the underclothing, and that the arm should be kept clean. If multiple vaccination is practiced, and three or more good marks are secured, a second vaccination is seldom successful to any degree in after-life, and I have never seen a patient so vaccinated have smallpox in any form in all of my experience. The reason that vaccination runs out is that it was never thoroughly run in, that is, the patient was only partially vaccinated to begin with. If the first effort at vaccination is incomplete it is difficult to secure a perfect result by later attempts.

After careful observation and a large experience I am convinced that the profession should return to the use of humanized virus, so far as it is possible to do so. This form of virus "takes" more certainly, produces less local and constitutional disturbance, and appears to give longer and better protection against smallpox. If the virus is obtained from healthy persons known to the physician, no better source for it can be conceived. The propaganda for bovine virus has always been largely a commercial one, and the sore arms and severe constitutional disturbance following its use is responsible for much of the growing prejudice against vaccination. Owing to its hygroscopic properties, and the consequent difficulty in drying the surface to which it is applied, if for no other reason, glycerinated virus is more objectionable than the dry points, but to my mind the time has come to abandon the use of the bovine virus, except in the emergency of an epidemic, or in starting a fresh stock of the humanized virus.

In conclusion permit me to say that in this day smallpox is a serious reflection upon the intelligence of any individual or community having it. Systematically enforced vaccination has protected every nation, army or community which has resorted to it. It is at least within the reach of every individual in this country who has arrived at the age of discretion. Smallpox is the easiest of all the contagious diseases to stamp out, even when it has gained a foothold. Prompt isolation of those affected, preferably always in a hospital, and the compulsory vaccination and surveillance of the exposed, has never yet failed to bring an outbreak under quick control.

These measures appear simple enough on paper, but their effective enforcement among negroes, and the class of whites who neglect vaccination and have a monopoly of smallpox, will fully test the tact, patience and firmness of the most experienced health officer. If these precautions could be rigidly enforced in the other states of the Union for six weeks we would have no smallpox. If successive generations were systematically vaccinated this loathsome disease would soon be no more known among men.

## LUNG DEVELOPMENT IN THE CHILD.

J. ALLEN GILBERT, PH.D., M.D.

PORTLAND, ORE.

The prominence of affections of the lungs in various diseases, either as complications or primary elements, gives this organ perhaps a higher importance than any other organ in the body. The emphasis given to tuberculosis is not the result of a mere scare, nor is the fear of it to be characterized as a simple "phthisiophobia" without sufficient foundation. Statistics show the danger only too plainly and until specifics are obtained for the cure of the various diseases the human race must resort to prophylaxis as its chief means of rescue. Even when cure is accomplished the result is obtained by attention to the individual as well as to the causative germ or agent.

It is not the intention of this article to discuss the degree to which pulmonary diseases are infectious, contagious or communicable but, accepting the fact that the lungs are a fertile field for the cultivation and spread of infection, to note a few points in which we are lax in employing the ounce of prevention, relying too much upon the pound of cure, which, in many instances, is short in weight.

The individual is often forgotten in the eager pursuit of the respective causative germs. There are two elements to be considered in etiology and prophylaxis: the external agencies, and the individual himself. It is difficult to decide which is the more important. Pathological conditions always depend upon the relative strength of the infection and the infected. Were it not for the vital resistance of the human tissues against external invasion, our history would have been written long ago. Prophylaxis for all infectious diseases can be summed up in the one principle of weakening the invader and strengthening the invaded. Relatively too much strength is expended in weakening and destroying the invader, leaving the individual fearful and defenseless in the presence of his self-induced weakness. Civilization is thrusting upon us our coughs and colds, our contracted chests, enfeebled stomachs and weak limbs: and often the higher in the scale the weaker is the resistance. The veterinary hospital gets a majority of its inmates from the highly bred animals, not alone because of their higher value—hence the attempt at preservation—but also because of their lack of resistance. Dr. Forehheimer of Cincinnati recommends for infant-feeding, not the milk of the highly bred Jersey cow, but that of the common, long-horned, sturdy, resistant, mountain cow—for her power of resistance. All nature is aggressive and it merely becomes a question of what forces shall conquer. Why do so many infants die? Lack of resistance. Prophylaxis is of most value in infancy and old age where resistance is at a minimum. The larger the city in which the child has his habitat the less likelihood of his winning in the contest, not alone because the strength of invading agencies is increased, but perhaps even more because his own powers of resistance are minimized. In the schools of our large cities where brush, broom and dusting cloth effectually scatter any infection to all parts of the room and where children of all grades gather from all sorts of environment we often find an ideal culture medium for infection. The value of space has crowded a large proportion of our city urchins into tenements where sidewalks and courts serve for playgrounds, where breathing space is at a premium, where the outlook is often so limited that the weakest arm scarcely dares to cast a

pebble for fear of breaking windows, where, echoing voices jostle each other in their struggle to reach the open air and where eyes accustom themselves to their narrow quarters and become near-sighted. Even where public parks exist the omnipresence of the "keep off the grass" and the stealthy encroachment of public buildings often rob the child of his natural gymnasium. His life is crowded with "don't's" until spontaneity of life is lost. Autopsy can pronounce his lung "a city lung" by the accumulation of soot; osteology distinguishes the country maid from the society lass and pathology establishes her museum in the slums where moral, physical and mental development are under the handicap. How far governmental interference is admissible or possible is a debatable question but there is always one place where corrective and regulative measures are possible to a certain degree, viz., in the schools. Education should be more than a mental development of the child. The magnitude of the task of providing adequate facilities for gymnastics for the children is a serious obstacle and yet the results would justify the attempt. Above all, children must be good animals. The blessings of a gymnasium are only too plainly seen by a comparison of the lung capacity of children in private and public schools. The advantage of the former, so far as development of the lungs is concerned, is enormous. The effects of a general physical culture on the body as a whole need no comment. One of a series of tests<sup>1</sup> taken by the writer on the school children of New Haven was the determination of the lung capacity for the respective ages from 6 to 17 inclusive. The data are based upon 100 children for each age. These children were without the advantages of a gymnasium and regular training therein. The accompanying table and chart represent a comparison of these results with those taken by Dr. Wm. G. Anderson of the Yale Gymnasium from children in private schools near New York. His results represent an average of 600 children at each age from 6 to 15 inclusive:

COMPARATIVE LUNG CAPACITIES FOR PUBLIC AND PRIVATE SCHOOL CHILDREN.

| Age.         | Boys.  |       | Girls. |       |
|--------------|--------|-------|--------|-------|
|              | Priv.* | Pub.  | Priv.  | Pub.  |
| 6 . . . . .  | 64     | 57.1  | 35     | 49.2  |
| 7 . . . . .  | 80     | 65.6  | 40     | 58.9  |
| 8 . . . . .  | 88     | 71.8  | 48     | 64.2  |
| 9 . . . . .  | 106    | 82.7  | 65     | 73.4  |
| 10 . . . . . | 124    | 92.8  | 80     | 80.3  |
| 11 . . . . . | 144    | 106.3 | 106    | 83.6  |
| 12 . . . . . | 150    | 117.2 | 125    | 104.6 |
| 13 . . . . . | 168    | 124.4 | 136    | 108.1 |
| 14 . . . . . | 188    | 120.4 | 150    | 107.8 |
| 15 . . . . . | 205    | 170.3 | 155    | 116.3 |
| 16 . . . . . | 205    | 189.3 | 155    | 119.9 |
| 17 . . . . . | 205    | 202.5 | 155    | 124.0 |

\* Priv.—Lung capacity of private school children in cubic inches.  
 Pub.—Lung capacity of public school children in cubic inches.

The children from whom his data were taken underwent a daily training in the gymnasium, and while on an average his children at 6 years of age had a slightly smaller lung capacity than the public school children, the increase in development of the former was so rapid that the children of the public school were soon excelled. At the age of 15 private school boys had a lung capacity of 205 cubic inches; public school boys only 170.3 cubic inches, the former having the advantage of 35.3 cubic inches. The average private school boy at the age of 15 had a larger lung capacity than the public school boy at 17. In girls the difference is even more

1. Studies from the Yale Psychological Laboratory, vol. II.

noticeable, for at 6 the girls of the private school have a smaller lung capacity than those of the public school, but they develop so rapidly that by the age of 10 the private school girls have a larger lung capacity; and thereafter the rapid development continues so that at the age of 15 they have attained 155 cubic inches, while public school girls show only 116.3 cubic inches, the former having the advantage by 38.7 cubic inches. The average private school girl at 15 has 31 cubic inches more lung capacity than the public school girl at 17. The chart shows an enormous difference in the development of the two classes of children. Had the lung capacity been larger at all ages in private school children it might be argued that the private schools received the children of the better classes and those who had athletic ambitions, but when it is remembered that at 6 years of age the average lung capacity of private school children is less than that of the public school children and that this relation is reversed within a year or two the argument in favor of the gymnasium in public school work would seem convincing.

The relatively slight increase in the lung capacity for girls subsequent to the age of 12 would seem to be a significant criticism of the prevalent fashion of lacing

rather than an indication that development of the lungs as such had in large measure completed itself previous to that time. Remembering the contracted breathing of the phthisical patient the above chart speaks loudly in favor of more attention to the physical in our schools. Mind and body are so intimately connected that neither may safely be neglected for the advantage (?) of the other. The value of deep inhalation is appreciated by insurance companies, for in all examinations they demand that the chest expansion be recorded; health resorts for the phthisical seek the places where the lungs can be thrown open, as it were, to the outside air; modern therapeutics in all lung diseases pleads for free ventilation and abundance of fresh air; every one knows that an organ in disease atrophies and yet we seem afraid of taking long breaths; seldom do we find the necessity of raising our voices above the loudness required to be heard across the reception room, and, to add to the handicap, fashion binds upon us its fiendish inventions calculated to restrict our natural freedom. We seem to have forgotten the truth that in order to be good men we must be good animals. As a rule the acute infectious diseases are acquired and not inherited and

a great majority of diseases of the respiratory system can be traced to insufficient consumption of fresh air. I repeat—nowhere is prophylaxis of more value than in the child. "As the twig is bent," etc. The place to attack the problem is not in the chest that has already surrendered but in our public schools where every child for a number of years is to a certain extent under public control. Gymnasias are a poor substitute for the ball field, swimming-hole and coasting hill, but let us arbitrate and compel the best terms possible from the civilization which refines to destruction.

## ROTARY LATERAL CURVATURE AND POTT'S DISEASE OF THE SPINE.

### DIFFERENTIAL DIAGNOSIS AND RATIONAL TREATMENT.\*

DANIEL W. MARSTON, M.D.

Instructor Orthopedic Surgery, New York Post-Graduate Medical School and Hospital; Surgeon to the Randall's Island, New York City (Children's) Hospital, and Daisy Fields Hospital for Crippled Children.

NEW YORK CITY.

From the time of Hippocrates, 500 B. C., until the present time the history of spinal surgery has been indissolubly linked with the general advancement of surgical knowledge. At no time, however, during all these centuries, so far as the writer can ascertain, has there been anything like an unanimity of opinion among medical men as to the proper treatment for these cases. In the time of Percival Pott all cases with kyphosis, even rapidly increasing, attended or unattended with abscess, were classed indiscriminately as Pott's disease. In this generation we have scarcely less erroneous statements from men who claim it is possible to cure cases of lateral curvature of the spine even after extensive bone changes have taken place. It is scarcely necessary for me to say here that these views are not now endorsed by representative surgeons. New ideas, however, even when sustained by unlimited pathologic and bacteriologic research and clinical experience, are often slow of adoption, and it is on this account that I purpose here to briefly differentiate, not only in the etiology and pathology, but also in the treatment of these two time-honored bugbears of the profession.

Not all cases supposed to be such are Pott's disease. Deformity, similar to that caused by tuberculosis of the spine, is seen following absorption from the Peyrier patches of the intestines in typhoid fever. This condition would be readily discovered in connection with a history of other typhoid symptoms. Another rare affection of the spine, resulting in kyphosis, is caused by the inoculation of the germs of actinomycosis. We also recognize a condition closely simulating tuberculous infection in acute osteomyelitis. This, however, differs from the more common condition, by its rapid onset and virulent and destructive course, in marked contrast to the insidious approach of tuberculosis, sometimes covering months and months. The germs of osteomyelitis will do in a few days what tuberculosis, as a rule, will not accomplish in many months.

These four conditions, each distinct, yet resembling one another in a few general symptoms, are commonly classed together as "Pott's disease." The consideration of those conditions of chronic stiffness of the vertebral column, as Bechterew's hyphosis and Marie's spondylosis rhizomelia, I purposely omit in this connection.

\* The author of this paper died at Niagara Falls, N. Y., June 9, having been taken ill on the way to the Meeting of the Association. He had intended to read this before the Section on Diseases of Children.

Their pathology, closely resembling rheumatoid arthritis, or as Dana claims, arthritis deformans, is not yet clearly defined.

#### ETIOLOGY.

The etiology of true tuberculous spondylitis is due to an infection of bacillus tuberculosis into an area of previous inflammatory action. This theory was taught by Phelps, in this country, and by Billroth, on the Continent, some years ago and is now the one generally accepted the world over. That the bacilli inoculate tissue not embryonic is impossible. The result is a slow growth of tuberculous tissue. As the area of inflammation extends inoculation takes place with destruction of bone. This was formerly known as caries, which is a term that means nothing and will eventually be dropped from the nomenclature of the subject.

The germs of tuberculosis enter the system primarily, as a rule, through the lymphatics. As described in an article on this subject written by the author and Dr. Phelps, a child, playing in the backyard of a tenement house, in an atmosphere contaminated by germ life, caused by the old woman beating the carpets from an infected room where an individual had died of tuberculosis or osteomyelitis, inhales the spores of the germ.

These spores are immediately absorbed by the lymphatics from the mucous membrane of the pharynx and the trachea and carried to the neighboring lymphatic glands. The lymphatic glands are rich with cells, and are a good soil for the reception and growth of the germ. The cells, or phagocytes, of the lymphatic glands are at once attacked by the germs and destroyed, until the entire gland is converted into a pus or tuberculous cavity, depending upon the kind of germ absorbed. These are the large glands seen in the necks of children and called by the older authors "strumous, or scrofulous gland." Ulceration now commences in the gland, burrowing takes place in the direction of least resistance. The gland is surrounded by a vascular network of veins and arteries. When perforation of the gland takes place from ulceration, its contents may discharge directly into the vein; thus it can readily be seen how the circulation becomes contaminated with germ life from the reservoir which is constantly discharging into it. Now, if the child playing in the backyard receives a slight injury of the spine, at once inflammatory action begins at the point of lesion already described. The blood being loaded with germs of infection carries them to the point of injury. The pathogenic germs, finding a fit soil for their reception and growth, attack the normal new inflammatory material and convert it into a diseased condition, with a formation of pus or a tuberculous abscess. From this point of local infection the pathogenic germs find their way into adjacent tissues, destroying them as they advance and enlarging the diseased area. Should the body of the vertebra be involved, as is the rule in a majority of cases, its partial destruction is simply a matter of time, *unless* the destructive process is checked by appropriate treatment, the focus of disease circumscribed, and ankylosis of the affected vertebrae accomplished.

Why is it that one child may receive a blow, but will not develop the disease, while a second child also receiving an injury will develop it, is an interesting question. It depends on the relative disease-resisting power of the cell life of the individual. In the one child the embryonic cells resist the attack of germ life, while in the other they succumb to the invasion of disease.

Rotary lateral curvature differs from tuberculosis of the spine. It is never produced by inflammation or disease of the spinal column. The etiology of these curves occurring high in the vertebral column, either in the dorsal or cervical region, is, I believe, nearly always congenital or rachitic. A rapidly-growing child who sits in a faulty attitude or stands in such a position as to constantly curve the spine, will often develop rotary lateral curvature.

Curves that occur in the lumbar region are usually due to such a cause as this, or to a shortened limb, or tilted pelvis. Paralysis of certain muscles may also be an important factor in the etiology of these deformities. I have known cases where great deformity resulted from the intercostal adhesions, following the absorption of a pleuritic effusion. Deformity of this kind is seen in the dorsal vertebrae, for the reason that the spine bends where there is a change in the ribs and in the muscles between the ribs.

The deformity in lateral curvature is produced by absorption of the vertebra from pressure. As the spine bends, rotation takes place always in the direction of curves. The body of the vertebrae always rotates toward the convexity of the curve. Then we say that nearly all cases of lateral curvature are to be considered as cases of lateral rotary spinal curvature. When more than one curve occurs it is then called double lateral rotary spinal curvature.

#### SYMPTOMS.

One of the most common symptoms of lateral curvature is the projecting shoulder-blade and the drooping shoulder. These are cases that find their way to various bandagers, who adjust worthless appliances, and the apprehensions of the mother are put at ease by such charlatans, until after a year or two when the orthopedist is consulted; he finds an incurable curve in the vertebra produced by absorption. Then the projecting shoulder-blade, the drooping shoulder, the prominence of the ribs on one side of the vertebra as the patient is bent forward, the absence of pain and spasm of the muscles, and the general good health of the patient are symptomatic of curvature.

In a case of tuberculosis of the spine the surgeon should always make a diagnosis before deformity occurs. To do this in a child only a year and a half old is sometimes difficult. In these cases, as a rule, there will be night cries; screaming of the child when the mother lifts it; bending forward of the body eliciting pain, anteriorly from the point of disease; the patient, placed upon its back, when lifted to an upright position with the hand under the head rising with a rigid spine; and in a sitting position, you standing behind it, the patient presenting a rigid spine when bent from side to side. If the disease is located in the lumbar region the good old doctor has probably treated the case for worms; if in the dorsal region for asthma. But when the symptoms which I have enumerated are present, although there is no deformity as yet of the spine, you could be quite certain in making a diagnosis of Pott's disease.

If the spine is flexible in its continuity there is no Pott's disease. If the spine is rigid it is certain to be present.

*Bone Changes.*—On one side the bodies of the vertebrae become absorbed by pressure, but on the opposite side they are normal. There is not a single straight spine in the world. If there were, the person would break his head every time he jumped six feet. Every

lateral curvature, to be cured, must have compensating curves so as to allow a vertical line to fall through the center of the curves and to fall inside of the base formed by the feet. In some lateral curvatures, as in rickets, the deformity is due to pressure. Ossification, as in the ossified man, about which so much was written in the lay press during the past summer, is produced by central nerve-lesions.

#### TREATMENT.

Treatment must be based on rational principles. I would treat lateral curvature with gymnastics and a support to relieve pressure. The support should be removed night and morning. Proper gymnastic exercises should be given and this too while the support is being worn. The corset should be applied before arising from bed in the morning, and not removed until the patient is again in bed upon retiring. The method sometimes practiced of giving exercises to curvature patients while without their spinal support is not correct.

In Pott's disease the treatment is operative as well as mechanical and constitutional. The new operation of forcible replacement, by Calot, France, was done by Hippocrates, was revived in the time of Ambrose Paré, in the 15th century, and again in this generation by Hadra, Galveston, Texas. This is a procedure adaptable only for selected cases, and at the hands of experienced operators. Long ankylosed cases, or cases in which abscess with much deformity exists, should not be broken up. In the early history of some cases forcible reduction has been of much benefit, but it is an operation attended with great risk.

The usual routine treatment consists of extension and fixation. The manner of accomplishing this end is along the same lines as in the treatment of rotary lateral curvature. The support is, however, not to be removed and calisthenics are forbidden.

It is a very good plan to always determine the extent of bone changes before beginning treatment. Bending forward shows it. A straight line along the back demonstrates the extent of deviation. The diameter of the vertebral column is two inches. If a displacement of one-half of this occurs to either side there is unstable equilibrium and exercise can not correct. The patient must be braced so as to produce stable equilibrium. A child of 3 years can not be properly braced, because the pelvis is too small as compared with the thorax and the brace will slip. Put on a Bonnet's cuirass, or better, Phelps' plaster-of-paris portable bed, which is good also in Pott's disease and hip-disease. Dr. Phelps got the idea from observing an Indian squaw carrying her baby. In spinal braces, when the band around the pelvis is narrow and small, the appliance will tilt. I believe suspension and then fixation is necessary. This is the principle of one brace invented in 1754. The Hessing corset was invented in 1764. Many apparatus modernized were used more than a century ago. Sayre was the first man in this country to make a suitable apparatus for Pott's disease or lateral curvatures, namely, the plaster-of-paris corset. It is good, but to its routine use in all cases of spinal disease, of all kinds, I have objections—it is heavy, cumbersome, unclean, and it wears out and so changes have to be made; but it is the best of all braces. Then there is the substitution of other materials for plaster-of-paris, such as leather, and cowhide, which proved unavailable, and wood, wire, celluloid and paper, none of which is of any value in

these cases. A spinal support must be *absolutely unyielding*, or it is entirely useless.

If the disease is located above the third dorsal vertebra, no corset or brace, without the aid of the jury-mast, can be adjusted so as to be a support, owing to the fact that the weight of the head and shoulders operates upon the point of disease or curve. In such cases the jury-mast must always be so adjusted as to transmit the weight of the head through the corset to the hips. The jury-mast does not lift the head but serves to tip it backward, transmitting the weight to the transverse processes and relieving the anterior border of the vertebral bodies, where the disease is, in the majority of cases, primarily located.

To make proper corsets from plaster-of-paris suitable material must be used. A hospital crinoline, which has the proper amount of sizing and material and a total absence of indigo is best. This cloth and fresh plaster-of-paris, when properly united, makes a perfect plaster bandage. Tear the crinoline into strips six inches wide and six yards in length, draw the cloth over a pile of plaster-of-paris, on a table, and with the hand rub off all excepting enough to simply fill the mesh of the cloth, roll the bandage loosely, that it may take water quickly, and it is simply perfection.

A tight-fitting shirt must now be adjusted to the patient. The shirt which we now use is a long stocking and costs about 25 cents a yard. The life or an ordinary jacket made of plaster-of-paris is about three or four months. They last longer in cool weather than when the patient is freely perspiring. Rapid setting of the plaster is necessary, because the hand holds it to the corrected position of the deformity. This material, with the stockinet, completes the materials necessary to make a perfect corset. The crinoline costs 6 cents a yard, the plaster-of-paris 3 cents a pound, and the stockinet 30 cents. A corset for a child 6 years old should weigh not to exceed one and one-quarter pounds, and for an adult two and three-quarter pounds. This makes a support as light or lighter than the steel brace, and it supports as a steel brace can not.

When the patient is suspended in Pott's disease of the spine, and a jacket properly adjusted, he is at once relieved from a condition of pain and suffering, and to such an extent that any amount of pressure upon the shoulders does not produce pain. In rotary lateral curvature of the spine, a plaster corset with lacings is made to fit this suspended and straightened position. After the corset has been adjusted the patient is three inches taller than before its application.

If the patient can afford the greater expense I always advise the aluminium corset, for, although the first cost is greater than for the plaster-of-paris support, yet, before treatment is ended, the metal appliance will have proved the cheaper. It is practically indestructible. Phelps calls it "the end of the law in spinal bracings," and I believe his statement to be correct. I do not suggest the aluminum corset as a substitute for plaster-of-paris in acute Pott's disease and lateral curvature. I suggest it rather to take the place of such braces in cases requiring permanent bracing, or in individuals who are desirous of securing a support at any time which combines durability with lightness and comfort. As soon as a case of lateral curvature has been arrested, or the greatest amount of benefit has been derived from treatment, the aluminum corset will then be found to be a most agreeable permanent support.

The aluminum corset has the following qualities to

recommend it to the patient: 1, lightness; 2, durability; 3, it is thin and does not interfere with the form and clothing; 4, being extensively perforated makes it the coolest and most agreeable of supports, and 5, the patient can wear it while bathing. An ordinary corset weighs from one to two pounds, depending upon the size. To prevent cracking and to protect it from perspiration it is covered with a waterproof enamel, which is applied by heat.

Steel corsets, somewhat similar to those of aluminum, were used by Ambrose Paré in the 15th century. Steel is, however, too heavy for practical use. It was necessary, too, to hinge the two halves of all metal corsets on both sides, beneath the axillæ. The duplex hinge used in our aluminum corsets at the New York Post-Graduate Medical School and Hospital was devised by Dr. Phelps, and by means of it the unequal planes of the corset are nicely hinged, enabling the patient to remove and re-apply the apparatus without assistance.

To make an aluminum corset, first make a plaster mold of the body. Fill this, and from the cast thus obtained an anvil of iron is made. Over the metal anvil the aluminum is hammered into shape. It takes two skilled workmen two weeks to make one of these corsets. When fitted to the body the corset is shellacked with a preparation that makes it impervious to perspiration. With an apparatus of this kind the patient can go in bathing. In Pott's disease the same kind of a corset can be used, if it is put on with wire lacing and kept on. In lateral curvature cases the corset is to be taken off daily and the patient instructed in proper gymnastic exercises. In Pott's disease the spinal support is not to be removed except at the surgeon's directions.

#### CONCLUSION.

In summing up, then, I may say that in rotary lateral curvature, in my opinion, the following points are to be observed:

1. Mechanical support and proper gymnastic exercises are to be combined.
2. The exercises are to be taken while the patient wears the support.
3. The apparatus is removed while the patient sleeps.
4. Where the deviation is more than half the diameter of the vertebrae an unyielding support is imperative.
5. After absorption of bone has taken place the primary curve can not be eradicated; the "cure" lying in the establishment of compensating curves, which maintain the equilibrium of the spinal column.

In tuberculosis of the spine, on the other hand, remember the importance of the following:

1. Fixation and extension are to be employed.
2. The existence of sinuses and abscesses do not contraindicate the immediate application of proper immobilizing apparatus.
3. Forceful correction of deformity is advised only in selected cases.
4. Finally, the success or failure in the treatment of either of these diseases is dependent largely upon the intelligence and willingness on the part of the patient; the care and help of the parents or friends, and prolonged watchfulness at regular intervals on the part of the surgeon.

---

Union, not division, is now the motto of the profession. Division and the multiplication of medical societies and medical colleges are the characteristics of a medical age which now is past. If medicine is to accomplish its appointed task, there must be harmony among physicians. The perpetuation of divisions means the delay of the full operation of the good tendencies in medical evolution.—*Cleveland Med. Jour.*

## SURGICAL CONSERVATISM OF THE OVARIES AND FALLOPIAN TUBES.

EDWIN RICKETTS, M.D.

CINCINNATI, OHIO.

Pathologic lesions of one or both ovaries and Fallopian tubes may be so serious as to call for the most radical surgical measures, even extirpation. There are cases in which extirpation is practiced unnecessarily by operators of limited experience and the conservation of these organs has not received the attention it deserves. It is of this incompetent work, which brings poor results and a high mortality, that I wish to speak. There can be no reasonable excuse offered, nor apology made, for the poor results obtained from the lack of true and intelligent conservatism. Many competent men have explicitly expressed themselves in this regard, but not through channels where their statements would do the most good. Just criticisms have emanated from many of the best men in general practice.

Hydrosalpinx was once recognized as a condition which demanded that the Fallopian tube be removed, together with the ovaries, whether diseased or not; for no macroscopic consideration of the ovaries under such conditions was deemed necessary. Conservatism for retaining, if possible, even one or a part of one of the ovaries, or tubes, or both, resorting to cul-de-sac vaginal drainage of hydrosalpinx, for the purpose of restoring tubal function, is now accepted by the best practitioners.

In suggesting conservative measures to an occasional operator recently, his surprise was marked, yet he advocates extirpation for the reason, I am sure, of his inability to do successfully such conservative pelvic work. In cases of congenital stenosis of the Fallopian tubes, causing sterility, that are diagnosed only after the abdomen has been opened for other reasons, dilatation of the tubes often results in a cure. In healthy Fallopian tubes, associated with a thick tunica albuginea, a free longitudinal and transverse incision, followed by dissection of the same, promises a cure for those ante-operative distressing symptoms of pain and general lassitude along with an exhausted nervous system. With a thickened tunic through which can be plainly seen protruding a few or a number of small flattened or round cysts, the ovary containing them may be retro-displaced and held firmly by bands of adhesions. To free the same by carefully dissecting them away and puncturing them often means success. He who always resorts to hysterectomy for fibroids, whether large or small, should not be regarded as a conservatist in pelvic surgery. Myomectomy in many instances, under such circumstances, may be chosen as the operation of election. Large myomas are successfully removed to save the uterus and the opposite Fallopian tube and ovary. In a recent case I was able to turn out through an abdominal incision, after incising the capsule, five medium-sized fibroids. I found that the sixth one had involved a portion of the anterior uterine wall, which extended from beneath the peritoneum to the endometrium, necessitating the performance of hysterectomy. Had the abdomen been opened earlier in the history of this case, I am convinced that all of these fibroids could have been removed and the uterus with its ovaries saved. As the ovaries were found to be healthy, they were not disturbed.

The influence exerted on the nervous system by the removal of the ovaries and Fallopian tubes during the child-bearing period is now more clearly understood

and more fully appreciated by the neurologist and surgeon. The testicle, which is the analogue of the ovaries, did not suffer so long from being removed, with the hope of relieving the enlarged prostate, as did the ovaries for the relief of pelvic pain.

We would freely criticize, from a scientific standpoint, any operator who failed to do complete work. Completeness must often end in the best conservative efforts within the pelvis, if the operator wishes to command the respect of the general practitioner, and through him the confidence of his patients and their friends. Failure to do this would mean that all true specialties must fall to the ground; consequently a high mortality would result.

It is not an easy question to decide promptly, even after the abdomen has been opened, which is the best operative procedure to undertake for the relief of any condition which may be found. One may have to resect, to drain, or to extirpate one or both ovaries with the appendages. From an operative standpoint, differential diagnostic ability must come from great and constant familiarity with pelvic surgery.

### Clinical Reports.

#### SOLITARY ABSCESS OF THE LEFT LOBE OF THE LIVER SIMULATING ABSCESS IN THE ABDOMINAL WALL.

CARL C. WARDEN, Ph.B., M.D.

NASHVILLE, TENN.

Thomas J., 44 years of age, had rheumatism ten years ago, from which he made a perfect recovery. He remained in perfect health and continued at active labor until the morning of April 24, 1901, when he complained of nausea and epigastric pain. He took salts and obtained a copious action of the bowels, which, however, did not afford relief. The next day there was a slight chill, some fever, pain and soreness in the epigastrium, anorexia and restlessness. On April 29 the symptoms were more pronounced. There were no subsequent chills, but the temperature had risen to 102.5 and the pulse to 100. Abdominal respiratory movements were free and equal on both sides. In the left epigastrium there was a tumor or bulging of the abdominal wall, circular in outline, hard, circumscribed and exquisitely tender to touch and percussion. The tenderness was very superficial, while deep pressure from below upward beneath the tumor was not so painful. I was unable to determine that the tumor dullness was continuous with liver dullness, and the mass appeared to remain stationary on deep inspiration. There was no fluctuation. The tumor seemed to be a part of the abdominal wall, very superficial and immobile. So far as could be determined the liver was normal in size, or at least that portion of the organ lying to the right of the median line. There was no jaundice, diarrhea or sweats.

In the attempt to reach a diagnosis two conditions were discussed. My consultants thought the case one of abscess of the left lobe of the liver, while I took the ground that it was abscess of the abdominal wall, basing my opinion on the following grounds: the absence of any of the ordinary causes of liver abscess, such as the amebic, traumatic, pyemic, cholelithic or cholangitic, and the negative history of rectal trouble, bone disease and diarrhea, together with the lack of proof that the tumor dullness was continuous with that of the liver, the absence of positive proof that the mass moved on deep inspiration, and the superficial appearance and character of the tumor. These arguments led my consultants to accept the diagnosis of abscess of the abdominal wall.

I operated on this patient at the City Hospital, May 2, 1901. A preliminary aspiration brought away pus. A vertical incision one and a half inches long was made directly over the center of the tumor and the peritoneal cavity opened without

finding pus anywhere in the abdominal wall. The left lobe of the liver presented in the wound, showing on its upper surface a marbled, white area the size of a nickel coin. There was a total absence of adhesions, and it was apparent that rupture into the general peritoneal cavity was imminent. The peritoneal cavity was carefully protected from infection by a cir-

cular wall of sterile gauze and the abscess opened and drained. The abscess cavity was the size of an orange; its walls soft, pulpaceous and shreddy except posteriorly where there was elasticity and rigidity. The pus was almost pure white, creamy and odorless. The cavity was wiped dry and packed with gauze to allow of removal and renewal of the protective wall of

Pulse.

The packing was then removed and two ample drainage tubes of rubber introduced and carried to the bottom of the cavity. The protective gauze was allowed to remain in place until the seventh day following the operation, when it was withdrawn, together with one of the drainage tubes. The remaining tube was gradually protruded and shortened until it

also was unnecessary. The patient was discharged May 24. He was seen by me Oct. 1, 1901, and gave a history of health and activity.

The etiology of this case is somewhat obscure. From the condition of the posterior wall of the abscess cavity one would incline to the opinion that there may have existed a latent ulcer of the stomach. The temperature record and the size and position of the tumor may be seen in the accompanying diagrams. Similar cases have been reported.

## AMPUTATION OF THE PENIS, FOLLOWED BY MULTIPLE PREGNANCY IN THE WIFE.

R. HARVEY REED, M.D.

ROCK SPRINGS, WYO.

Three years ago, J. K., a Finlander, aged 35, was admitted to the Wyoming General Hospital for disease of the penis. I was obliged to amputate the organ, leaving a stump after recovery of about one inch in length. Approximately one year after his discharge from the hospital, his wife, a small, healthy Finlander, of some 30 years, gave birth to a healthy male child. Being somewhat suspicious that the child might be illegitimate, I questioned the wife very closely, and was doubly assured that such was not the case, but a legitimate product of her husband.

About one year later, she had a miscarriage, which was followed by metritis, which I treated with every indication of permanent relief.

On April 1, 1902, I was called to see her and found that she was suffering from a threatened miscarriage. On April 6, I delivered her of a five months' fetus. As her surroundings were bad, I had her taken to the Wyoming General Hospital, where she was delivered of two more five months' male fetuses during that night, and on the next morning, April 7, she gave birth to a fourth. Recovery was rapid and unattended by anything remarkable, and the patient was discharged April 13 in good condition.

It would appear from this case that neither the length of the penis nor its normal condition have much to do with impregnation, so long as the semen of the male and the genital organs of the female are in a healthy condition.

## VICARIOUS MENSTRUATION FROM THE RETINA.

J. G. HUIZINGA, M.D.

Formerly Professor of Ophthalmology of the Post-Graduate Medical College and Hospital, and Oculist and Aurist to Cook County Hospital of Chicago.

GRAND RAPIDS, MICH.

I desire to report a case of vicarious menstruation that occurred in my private practice six years ago.

Miss R., aged 17; occupation, house work. Both parents are living and are healthy, hard-working people. There is no history of specific trouble or any other hereditary disease. She has never been sick, is strong, robust and well developed. Her menses appeared when she was 14. They were somewhat irregular at first, but had been fairly regular for the last year and a half. They were usually accompanied by headache, some backache and a feeling of indisposition. These symptoms were never sufficiently severe to confine her to bed. During the first day of her October menstrual period, while stooping forward to fasten her shoe, she suddenly felt dizzy and nearly fainted away. Everything she looked at seemed distorted and her vision became dimmer and dimmer. Apparently the left eye was first affected, followed in a few minutes by a similar condition in the right eye. That afternoon she consulted me and I found the appearance of the fundus to be that of hemorrhagic retinitis with numerous blood spots scattered over the field. The optic disc was slightly inflamed and its borders rather indistinct. There were a few clots in the vitreous. The external appearance of the eye was that of an ordinary conjunctivitis. Vision in the right eye was 5/200 and in the left eye 10/200. A tight cold compress was immediately applied and instructions

given for a warm sitz bath three times a day. The artificial leech was applied to the temples and about two ounces of blood removed from each side. Potassium bromid and potassium permanganate were given internally and free catharsis established. The menstrual period passed without further trouble. The conjunctival congestion disappeared, the vitreous cleared, and the larger hemorrhagic spots in the retina changed into atrophic ones; the others disappeared without leaving a trace. But before this transformation had been completed the time for the next menstrual period had arrived and with it a repetition of the same phenomenon. The same treatment was instituted as before only to be followed by another and a last hemorrhage in December.

## New Instrument.

### A NEW ADENOID CURETTE FORCEPS.

WILLIAM A. MARTIN, M.D.

SAN FRANCISCO, CAL.

The instrument here described is one on which I have been working at intervals for the past two years, and which has been remodeled a number of times. The present instrument is light and graceful and works almost perfectly. I can not say that it will displace all other instruments used for the same purpose, but it will do better work than any other single instrument. I assert that in the majority of instances it will remove the whole growth in one piece, that its use will be followed to a minimum hemorrhage and that no injury can be done to the septum, turbinates or pharyngeal walls when used

with ordinary skill. There is little pain following its use compared to that which follows the repeated thrusts necessary in the use of the Gottstein curette and there will be no fragments left hanging to slough away and cause secondary hemorrhage. Furthermore, one has the satisfaction of exhibiting the specimen to the parents, who are not always satisfied with the explanation that the growth has been swallowed. I have had the instrument made in two sizes as some of my colleagues suggested that the smaller would not do the work in all cases. Thus far, however, I have not encountered a case where I could not do the work satisfactorily with the smaller one.

135 Geary Street.

**The Sample Nuisance.**—One of the minor afflictions of modern life is that curious form of commercial enterprise which manifests itself in the wholesale distribution among householders of samples of products, medicinal, dietetic, disinfectant, and what not. Doctors are naturally marked down by dealers in such wares as their natural prey. Sometimes the samples are sent by post, sometimes they are left, like superfluous babies, on the doorstep. The thing is a distinct nuisance, and might easily become a danger. We are glad to see, therefore, that America, from which this mode of advertisement comes, is taking the initiative in attempting to check it. —*British Med. Jour.*

# THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

61 Market Street : : Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, MAY 31, 1902.

## THE HOUSE OF DELEGATES.

On the tenth of next month there will gather at Saratoga Springs, N. Y., a body of men that will be unique from the fact that it will be the first time a national body of medical men ever met that was created in a strictly representative manner. There have been larger gatherings of physicians from the various states, but they were largely self-appointed, and some states had a much larger proportionate representation than others. The House of Delegates of the American Medical Association, however, will be composed of men elected to represent a definite clientele, and a definite territory.

For years those who have been most anxious for success in medical organization, and have desired that the American Medical Association should be more representative in character and of greater influence, have insisted that its legislative branch should be a body in which should be federated the state societies. The House of Delegates will be just such a body. It will be truly representative of the whole country; it will be a body in which will be federated the state and territorial societies. It will be a large committee created by the state societies in proportion to their membership. It will be the mouth-piece of all the state and territorial societies, the exponent of the profession of the whole country.

As such, the responsibilities of its members will be very great, and, while to belong to it will be an honor, the duties will probably be found to be onerous. Especially will this be true as it applies to those who desire to attend the sections and take part in the scientific work, for this they will not be able to do. There are some extremely important questions to be considered, and to consider them will require time. Under the old order, all subjects which were likely to develop an interminable debate were laid on the table by the general meeting; the House of Delegates will discuss these questions deliberately. Vexed questions, such as that pertaining to the Code of Ethics, etc., which were liable to develop acrimonious discussion, were not allowed to come before the large meeting which constituted the old legislative body, if it were possible to prevent; the new legislative body will be able to consider such questions calmly and dispassionately. There are some important problems to be solved in the general plan of reorganization now going on, and these will require much thoughtful consideration. The questions of reciprocity, of a voluntary national examining board, of the regulation

of medical colleges and medical education—these and other important problems will come before the new body representing the medical profession of this great country.

We repeat, to be a member of the House of Delegates of the American Medical Association will be an honor; at the same time the position is a most responsible one, the duties of which should not be lightly considered. These duties will not only be arduous but time-consuming and will require much self-sacrifice on the part of those who assume them.

We print elsewhere the names of those thus far selected and reported who will constitute this new House of Delegates. A glance at these names will reveal the fact that this body will be representative in another way than was meant above; it will be representative of the best there is in American medicine. Each state seems to have selected its representative or representatives from among its best members; and the sections also. Those who read these names and know the men will have no fear that the first House of Delegates of the American Medical Association will in any way disappoint those who expect much from that body's deliberations.

## NURSING AND THE PHYSICIAN.

An American humorist said not long ago: "If the Christyans had some science an' the doctors more Christyanity, it wudden't make any difference what ye called the disease—if ye only had a good nurse." The passage, of course, has been much quoted. It is only with the last phrase that we have any fault to find, and that solely because, while containing a modicum of truth, it is liable to render still more popular than before the wrong interpretation of an expression often, unfortunately it seems to us, used without exact definition of its meaning, even by physicians themselves. In recent years we frequently hear the expression, "What is needed is good nursing." With regard to the specific fevers that run a definite course and are self-limited, the expression is very appropriate. The public and the medical profession, however, understand the maxim in entirely different senses. The physician means that as yet we know no specific treatment for the disease and that what is necessary therefore is careful and unremitting symptomatic treatment. The public mistranslates the expression somewhat inconsequentially into the idea that the doctor feels himself powerless in the presence of the disease; he can not cure it, he can not abort it, he can not even materially shorten its course and so he frankly and disinterestedly, though a little unwillingly, concedes that the only hope is in the nurse's careful ministrations. Nothing could well be further from the truth than this entirely erroneous impression.

There is an interesting palimpsest of meanings in the word "nurse." To nurse meant originally to nourish with breast milk. How much wider the signification of the word has become may be best judged from the fact that now the verb may be used with a connotation of the

other gender also and has come to have as an appropriate definition "to husband the strength."

By good nursing is meant every possible care of the patient. Symptoms that reduce the patient's vitality must be met, the strength must be conserved, every source of annoyance that may sap nerve force must be, as far as possible, removed. The bowels must be kept in order, the appetite must be aroused if the fever continues and threatens to exhaust the patient and, finally, sufficient nourishment must be ingested in some way, if necessary, extra-orally, to keep the balance of vital energy from sinking below a dangerous level. In a few words, "nursing," or symptomatic treatment, must do all that the older physicians insisted on as curative and must do it in that broader and more rational way that uses every force of nature to the best advantage in the combat with disease.

Needless to say, the problems involved in this active care for patients, include thorough familiarity with every resource known to modern medical science. Good nursing implies the use not only of all the natural therapeutic measures, but also of the drugs suited to the case, and even of the less serious manipulations usually classed as surgical. It is in this wide sense that the physician talks of the benefits to be derived from good nursing. The public must not be allowed to drift into error in the matter. Undoubtedly, the institution of the trained nurse and the improved nursing conditions in our hospitals have greatly lessened the mortality from the specific infectious diseases, and especially the prolonged fevers, but this is so only because of the constant sedulous supervision of trained medical skill. Instead of lessening the need for the physician's attendance the more general employment of nurses has emphasized the advisability of noting even slight changes in patients' conditions and of meeting symptomatic indications before they become actual complications.

The ounce of prevention that is worth a pound of cure now has a chance to be applied as never before. The constant watchfulness that is the essence of good nursing keeps the physician so well informed of even passing conditions that no important indication for his services is missed, or even put off for a short time to the patient's detriment. This, and not the falsely assumed interpretation of the word that would ignore the most hopeful, helpful elements in present-day medical practice is the true modern meaning of the word nursing.

#### GELATIN AS A FOOD AND THERAPEUTIC AGENT.

Gelatin is an albuminoid substance obtained by boiling skin, connective tissue and bones of animals in water. When taken alone it has but little value as a food. Animals fed upon it exclusively rapidly lose strength and weight and finally die from starvation. If it is added to other foods it possesses the property of limiting the consumption of non-nitrogenous materials and saving the waste of albuminous tissues. It takes no part in the repair and growth of tissues and must be considered

solely as an "albumin sparer." Consequently gelatin must always be combined with other proper foods. It does not replace albumin, and the destruction of albumin takes place to some extent even when gelatin is taken in a large amount. Gelatin is easily dissolved and absorbed from the stomach, and is usually taken in the form of jellies flavored with coffee, fruit juices, sherry wine, etc., and it may be rendered more palatable by the addition of meat extract. Brat<sup>1</sup> has recently reported, from Leyden's clinic, the preparation of a gelatose, obtained by the action of acid upon gelatin at a high temperature. This substance is soluble in cold water, and can be administered in solutions with a flavoring of fruit syrups, etc., in much larger quantities than gelatin will be tolerated.

The special indications for the employment of gelatin as a food are not entirely clear. As to its use in diabetes mellitus there is some difference of opinion. Senator advocates its use in this disease as it has been shown to be a weak glycogen builder. In intestinal putrefaction it may be employed with advantage since no indol or phenol is formed from it as a result of bacterial action. It is generally recognized as a useful addition to other foods in the diet of fever cases. G. Klemperer points out that gelatin is contra-indicated in cases of oxaluria and oxalic renal calculi, as it gives rise to oxalic acid and causes its increase in the urine.

During the past five years, clinical evidence has been accumulating which indicates that gelatin, when injected hypodermically in solution, has a marked influence in increasing the coagulability of the blood. It has proven especially valuable in cases of hemophilia and aneurysm. Successful hemostatic results have been reported to have followed the administration of gelatin by the mouth, but the cases have been few and not perfectly convincing. The results of some investigations by H. C. Wood, Jr.,<sup>2</sup> on the effects of the digestion of gelatin on its styptic properties are of much value in placing the administration of gelatin by mouth for hemostatic purposes upon an intelligent basis. He found that pepsin digestion of gelatin does not destroy its coagulating effect on the blood. The product of such digestion is dialyzable and therefore capable of absorption, and the administration of gelatin by the mouth in the treatment of hemorrhage is therefore a rational procedure. These facts are of special importance in view of recent observations of cases of tetanus following the hypodermic injection of gelatin and of the demonstration of tetanus bacilli in many samples of gelatin.<sup>3</sup> If gelatin is to be administered to man by hypodermic injection it is advisable to first test it upon experimental animals to determine the absence of tetanus bacilli and their toxic products. It would be desirable for manufacturers to furnish the profession with gelatin, which had been sterilized and properly tested, in some convenient form so as to be ready

1. Deutsche Med. Woch., Jan. 9, 1902, 21.

2. American Medicine, May 3, 1902, 729.

3. JOURNAL A. M. A., March 8, 1902, 651, and March 15, 1902, 740.

for immediate use. If future results show the introduction of gelatin by the mouth to be as satisfactory as the hypodermic injection, the danger of tetanus can be eliminated by employing the former method.

#### THE SEED AND THE SOIL.

In a recent number of the *Lancet*, Dr. W. Howship Dickinson reviews certain facts with special reference to the germ theory of disease, in what seems to us a very sensible way. At the present time the discovery of a microbe in a disease conforming to the recognized criteria of pathogenicity, is too commonly accepted as ending discussion as to its treatment—we must keep out the germ of infection and the disease is conquered. Hence, the premature and exaggerated deductions as to the importance of isolation, disinfection, etc.—all measures good in themselves and absolutely essential in many infections, but by no means so much so or so beneficial in certain others where their all-importance is at the present time so much agitated. We must keep in mind that the soil as well as the seed is essential and the human organism does not in all cases and at all times furnish the same pabulum and foothold for the germs. They may sometimes fall on stony ground or the thorns of other more or less serious pathologic conditions may overwhelm them. In every epidemic and with every infection there are those who are immune, often only the insignificant minority are susceptible. Dickinson discusses these facts, using as an apt illustration the well-known microbial disease, relapsing fever, which depends so absolutely for its occurrence upon the non-resistance favoring environment that non-nutrition, etc., can supply; that its accepted synonym is famine fever. The most attention, however, is given by him to tuberculosis, which he considers stands first as a striking example among diseases of the importance of susceptibility as a determining etiologic factor. The microbe, though the undoubted cause of the disease, is of secondary importance; it is not so much the bacillus as the reception offered to it that needs to be seriously considered. This depends upon various factors, first among which Dickinson recognizes heredity as of unassailable importance, then come local inflammatory conditions, such as pneumonia or capillary bronchitis and influenza, irritant inhalations, alcoholism, exhaustion and depression, damp sub-soil, overcrowding, and insufficient ventilation. Without these singly or together the microbe is harmless as a rule. "We can imagine," says Dickinson, "an isolated item of humanity on some mountain summit or isle of the ocean congratulating himself if on nothing else on his exemption from tubercle, but in common social conditions the seed is sown broadcast and the vital question is not where it will be deposited, but where it will grow." There is danger, as he says, that we may have too much thought for the microbe and too little for the man, and in the contest between the two it is more to the purpose to support the man than to attack the microbe. As a rule, the bacilli of the disease are out of our direct reach, but we can make, he thinks,

the conditions so unfavorable for their existence in most cases that they will have to succumb. There is abundant evidence that our systems are constantly getting the better of diseases that we consider hopeless, and even cancer has been reported to have undergone, in rare cases, a spontaneous cure. The antitoxins are also used by Dickinson as an apt illustration of the law that the seed is impotent if the soil is unfavorable. They do not destroy the bacilli: the diphtheria bacillus he is assured will grow in its antitoxin, but they somehow or other so modify the blood and tissues as to render them no longer capable of supporting the germs. He would not be understood as ignoring the latter for we can do something by excluding them, and we may even hope to see some of them exterminated. There are two sides, however, to be looked upon in the management of diseases, the attacking organism and the resistance, and both must be considered. We have of late perhaps relied too much upon direct frontal attacks on the enemy in some diseases and tuberculosis may be one of these. It is well that we should be occasionally reminded to reform our strategy. The optimistic notion that by isolation, etc., we can stamp out tuberculosis seems very little warranted when we have in mind its widespread distribution throughout the animal kingdom: but we are learning facts every day that make it seem less formidable. We have already a partial immunity and it may be that with further knowledge of the disease we can make it far more nearly complete.

#### SERUM DIAGNOSIS APPLIED TO PULMONARY TUBERCULOSIS.

Of the curability of pulmonary tuberculosis there is no longer any reasonable doubt, but the prognosis will in general depend upon the promptness with which the individual case comes under observation and is subjected to treatment. Any means, therefore, that will contribute to the early diagnosis will, by so much, facilitate recovery. Often the disease will have made considerable progress before the appearance of physical signs sufficiently distinctive to explain the obscure symptoms present. The tuberculin test, although valuable, is not entirely free from risk and care must be exercised in the interpretation of its results. The utility of the serum-agglutination-test in the diagnosis of typhoid fever has suggested the application of the same expedient to other diseases, among them tuberculosis, but here there has been a wide divergence of opinion.

Observations have been recorded to the effect that the blood serum of certain animals treated with tuberculin or with attenuated cultures of tubercle bacilli and also the serum of many tuberculous patients, as well as tubercular exudates, is capable of causing agglutination of bouillon-cultures of tubercle bacilli. Results of an opposite character have, however, been reported by other observers. For the purpose of determining which of these views is the correct one, Dr. Francesco di Grazia<sup>1</sup>

1. *Berliner klinische Wochenschrift*, March 17-24, 1902.

undertook a series of investigations that led to the conclusions, 1, that the blood serum of many animals with certainty free from tuberculosis is capable of causing complete or incomplete agglutination of cultures of tubercle bacilli; 2, that the blood serum of persons suffering from various non-tubercular diseases is equally capable of causing agglutination of cultures of tubercle bacilli in the same dilution as the blood serum of tuberculous patients; 3, that the blood serum of patients suffering from pulmonary tuberculosis is capable of causing agglutination of cultures of various kinds of bacteria, at times in greater degree than cultures of tubercle bacilli, at other times in almost the same degree and at yet other times in lesser degree. Similar results were obtained with emulsions of dead tubercle bacilli. It was found, further, that the reaction between the blood serum of tuberculous patients and cultures of tubercle bacilli or emulsions of the dead bacilli may be positive and intense in advanced cases and in those approaching a fatal termination, and slight in the mild and incipient cases, in the absence of any constant relation between the degree of agglutination and the stage of the disease.

The phenomenon of agglutination thus appears from these later observations to be of little or no significance in its bearing upon either the diagnosis or the prognosis of pulmonary tuberculosis.

#### IDIOPATHIC OR CONGENITAL, HEREDITARY AND FAMILY HEMATURIA.

Hematuria with no apparent or demonstrable cause has been the subject of considerable discussion, and one explanation for some of the cases was mentioned editorially<sup>1</sup> in a recent issue.

L. G. Guthrie<sup>2</sup> has reported a most interesting series of cases of hematuria occurring in two sisters and eight of their children. Blood was noticed in the urine soon after birth and persisted for years. The amount of blood was variable, sometimes being sufficient to impart a bright red color to the urine and again being recognized only by a microscopic examination. In all the cases there occurred paroxysmal exacerbations of the hematuria accompanied by slight pyrexia, malaise, headache, vomiting and slight pain in the back or limbs. These paroxysms could not usually be ascribed to any certain cause and occurred at night as well as during the day. None of the usual symptoms of nephritis were present. The excretion of urea was normal and the hemorrhage could not be connected with the presence of uric acid or oxalates. The urine was normal in quantity and specific gravity, acid or neutral in reaction, and usually contained from one-twentieth to one-fourth of its bulk of albumin. The sediment contained normal blood corpuscles, tubular blood-casts in greater or less abundance, but never other varieties of tube-casts. No case of the series showed any other evidence of hemophilia. All the local causes of renal hemorrhage were excluded. Some of the children in the families escaped.

Somewhat similar cases have been previously reported, but they have lacked the congenital and hereditary character. Attlee has recorded three cases of recurrent hematuria occurring in one family. Durante has observed cases of cyclic hematuria in children in which no cause for the condition could be ascertained, and he concludes such to be instances of simple or idiopathic renal hemorrhage analogous to epistaxis.

The etiology of the hematuria in these cases is obscure. The local causes appear to have been satisfactorily excluded. Durante suggests the idea of a developmental defect in the walls of the renal capillaries. Guthrie thinks the most reasonable explanation to be the existence of some inherent weakness or varicosity of the walls of the renal vessels. The analogy between this condition and hemophilia is very striking. In some cases of hemophilia an abnormal thinness of the vessels has been found, and in some instances the tendency to excessive hemorrhage has been confined to certain parts of the body. It is possible that in these cases of idiopathic hematuria, the abnormal condition of the vessels, corresponding to those found in hemophilia, are located in the kidneys alone. It is difficult to imagine any toxic agent acting in so many members of two families, and not more often showing its effects in a similar manner in other persons.

#### RATES TO THE SARATOGA MEETING.

As we go to press, we learn that a rate of one fare plus two dollars will be made for the round trip to the Saratoga Springs meeting. The Lake Shore & Michigan Southern Railway, in connection with the New York Central Railway, has been selected by the Committee on Transportation as the official route from Chicago and the Chicago Medical Society will run a special train, leaving Chicago at 11:30 a. m., Sunday, June 8. This will afford an opportunity for those who avail themselves of it to materially reduce their expenses and ought to favor a largely increased attendance. Under Association News will be found full details as to sale of tickets, time of return, etc. This reduction applies to roads east of Chicago and it is presumed will also be extended to those farther west. The Committee of Transportation deserve praise for their continued efforts in the matter. The Lake Shore Road has given valuable assistance and has exerted a leverage upon the eastern roads that has aided greatly in securing their concession. Let us make the Saratoga meeting the largest and best ever held.

#### HONORARY MEMBERS.

The new Constitution of the American Medical Association provides for the election each year of not to exceed three honorary members who "shall be physicians of foreign countries who have risen to preëminence in the profession of medicine." It also provides that these shall be elected by the House of Delegates on the nomination of a Section. It will be well for the various sections to remember this new provision. It is presumed that each Section that desires to do so will select some noted foreigner working in the particular branch of medicine represented by such Section and recommend

1. THE JOURNAL A. M. A., May 17, 1902.

2. Lancet, May 3, 1902, 1243.

such to the House of Delegates for election to the position. There should be an effort made to elect as honorary members of the American Medical Association only the best men in the old world and it should be an honor for whomever receives the distinction. We would suggest that the various Sections take this matter up at their first meeting so that the recommendations can be made to the House of Delegates not later than Thursday morning.

#### THE ANNUAL MEETING.

The Saratoga meeting, the first in New York State for more than twenty years, ought to be—and promises to be—well attended. Occurring as it does at a popular summer resort with ample accommodations and many local attractions, it will afford a specially favorable opportunity for physicians to utilize it in their annual outing, of course without neglecting the scientific and professional opportunities of the meeting. The present is a suitable time for members to endeavor to interest their professional colleagues in the Association, which, while it has now over 11,000 members, should include a still much larger proportion of the profession. If each member made himself an active missionary for the increase of the membership the outsiders would soon be the exceptions and not the rule, and the Association would be the grandest and most powerful medical organization the world has seen. With all its growth up to the present its future is yet all before it and the possibilities are only limited by the good will and activity of its membership. The attention of members is called to the advertising pages 47 and 48 in this issue, where blank forms for application, etc., are given. An earnest effort at the present time will count much for good.

#### A VOLUNTARY NATIONAL EXAMINING BOARD

One of the arguments against the practicability of the proposed national examining board is that the states will not recognize its certificate. If the medical profession wants such a board, and wants its certificates recognized by every state, then we can have such a board and its certificates will be recognized by every state. It is the medical profession that has put the medical laws on the statute books of the various states: there is not a medical law but that became such through the exertions of the medical men. If the profession wants these laws modified, it can have them modified. If a national examining board shall be created, and the influential members of the medical profession in each state will ask to have its certificate recognized, its certificates will be recognized. There is not a particle of doubt about it. The first thing needed, evidently, is to educate the members of the profession to appreciate the importance of such a national board; this done, the rest is easy. If the certificate of such a board represented a standard of education higher than that of any state board of examiners there would be no difficulty in having such recognized.

#### EMPLOYMENT AS A THERAPEUTIC AGENCY IN PUBLIC INSTITUTIONS.

If there is any fact known as a certainty to alienists and penologists it is that rational employment of those whose condition will permit is conducive to mental health

or improvement. Without it our prisons would become culture-beds of dementia and one of the most valuable therapeutic resources of our asylums would be wanting. Notwithstanding this fact it is sometimes a question how this means for good can be made available and the difficulty is increasing. In times past some of our state penitentiaries have been made self-supporting by the labor of the prisoners and the discipline and general welfare have been greatly facilitated and improved. Of late years, at least in many states, the demands of the labor leaders have seriously embarrassed the prison managements by inducing the enactment of laws against prison labor: indeed, it is only by makeshifts and sometimes possibly by evasions of such laws that the authorities manage to keep up the discipline and health of their establishments. So far the asylums have mostly escaped the notice of the labor unions, but recently we have seen a complaint that work that might be done by outsiders was being performed by patients and it is quite within the possibilities that any such work in the future may also be prescribed. While it would seem unreasonable enough to forbid the medical prescription of employment at some useful labor, there are precedents that threaten even this. In the case of penitentiary inmates the question is a living one at the present time: no one questions the need of rational employment for their health, but provisions for this purpose and compliance with the law are hardly reconcilable under the legislation of some states. The profitable employment of a considerable portion of the chronic insane is practicable and desirable and its comparative neglect in our asylums thus far has been greatly to their injury. It would be unfortunate that action based on the realization of this fact should be embarrassed by class legislation. The matter is one that ought to interest the medical profession which should use its influence judiciously for the welfare of the unfortunate and the public welfare. It is not good political economy to increase insanity or to make it incurable.

#### PROPHYLAXIS IN INFECTIOUS DISEASES.

In the diseases usually spoken of as contagious it has been customary to insist upon rigid prophylactic measures to prevent the dissemination of the infectious agents. Some other diseases, which at times are transmitted directly from person to person, have received little attention in this direction. Among the diseases referred to may be included pneumonia, tonsillitis and influenza. The clinical observations of a considerable number of physicians furnish almost incontrovertible evidence that lobar pneumonia is something due to the infection of a healthy person by pneumonic sputum. This is especially liable to occur in the person of the nurse or attendant upon the sick, the necessary susceptibility being produced by loss of sleep and general exhaustion. In follicular tonsillitis the evidence of contagion is as convincing as in the so-called contagious diseases. There is no question that influenza is contagious. Because the danger of contagion in lobar pneumonia is not usually great and because follicular tonsillitis does not usually endanger life, the necessity of adopting measures to prevent the direct contagion of these diseases has not usually appealed strongly to the physician or to

the laity. In all of these diseases the danger of infection could be very much reduced if care were taken that the infected material thrown into the air in coughing, etc., were not allowed to enter the mouth and throat of the attendants, and if the sputum were carefully disinfected, and the hands sterilized after being contaminated by the secretions from the local disease, especially before eating. It is scarcely desirable to adopt such thorough isolation, etc., as are required in the more eminently contagious diseases, but by relatively simple measures many cases might be prevented.

#### CHURCH HYGIENE.

Our contemporary, the London *Lancet*, calls attention to the aid in combating infectious diseases which may be afforded by the clergy through their influence over the laity in such matters as vaccination, ventilation, etc. This general influence over individuals is not the only way in which the clergy may aid in obtaining better hygienic conditions, for they may also do much to further the introduction of proper conditions of hygiene into church buildings and services. It is certain that infectious germs are carried into churches by attendants at services and if the buildings are damp and little sunshine and fresh air gain entrance, as is too often the case, the conditions are very favorable for these germs to remain alive and capable of producing infection when opportunity occurs. Besides microscopic agents of this kind, there are also carried into churches larger animal parasites, which have been often observed in churches since the days of Burns. Efforts should be made to rid church buildings of both the infectious bacteria and vermin by thorough airing after services and by the frequent employment of antiseptic washes and other measures used in private and other public houses. Simple furnishings in churches, such materials being used as can be properly cleaned, would much facilitate this. There has been a commendable effort among some of the church authorities in Italy to introduce the sanitary measures indicated, and they have not overlooked the holy water which has often been found badly contaminated. The water is to be frequently renewed after careful cleansing and disinfection of the receptacle. The common communion cup has met with much disapproval from a sanitary standpoint, and the subject has been referred to in *THE JOURNAL* on several occasions. It is gratifying that individual cups are gradually being introduced into the protestant churches throughout the country.

#### THE BACTERIOLOGY OF THE NOSE IN HEALTH AND DISEASE.

Systematic bacteriologic examinations of the mucous membrane and contents of the nose would seem to offer important results. The nose is frequently the seat of inflammatory processes of an acute character that often appear to extend to neighboring cavities and membranes and that even may seem to be the starting-point of important internal infections. The comparisons between the bacteria of the healthy nose and those of acute rhinitis might throw some light upon the etiology of the latter, all forms of which are probably not of the same importance. It is consequently not without value to

note the results recently published by Neumann<sup>1</sup> of careful examination of 206 persons. In 111 the nasal mucosa was normal, in 95 the seat of some recognizable lesion. Nineteen different species of bacteria were found, the most common being pseudo-diphtheria bacilli (in 98 per cent. of the cases) and white micrococci (86-90 per cent.). There were also found yellow micrococci, pneumococci, streptococci, diphtheria bacilli, Friedländer's bacillus, etc. The pseudo-diphtheria bacillus appears to be a constant inhabitant of the nose; it was not found to be virulent in any of the cases of this series which were freely examined on that point by means of inoculations of guinea-pigs, and it must be regarded merely as a harmless saprophyte. In acute coryza the pneumococcus, streptococcus, Friedländer's pneumobacillus, and the diphtheria bacillus are more conspicuous and more frequent than in the healthy nose, and Neumann regards it as definitely established that virulent diphtheria bacilli and the pneumococcus may produce the clinical symptoms of coryza. His investigations do not lend support to the idea that coryza is caused by a specific germ and favor the conception that ordinarily it is a more or less superficial catarrhal affection. It is important to know that virulent diphtheria bacilli may cause acute coryza as well as the so-called rhinitis fibrinosa.

#### THE DIAGNOSTIC VALUE OF AGGLUTINATION IN MIXED INFECTIONS.

Mixed infections are frequent in typhoid fever, and as this disease is the one disease above others that calls for the agglutination reaction as a diagnostic measure, it becomes of value to know what influence, if any, mixed infection may have on this reaction. Castellani<sup>2</sup> studied this question experimentally. In one series of experiments he injected rabbits with two different, agglutinable bacteria at the same time, such as the typhoid bacillus and the colon bacillus, the typhoid bacillus and the bacillus of dysentery, etc. He found that the blood serum acquires agglutinating properties for all the bacteria injected, the time of appearance, intensity and duration of the agglutination of each bacillus being identical with the conditions observed when only one bacillus is injected. He then established a single infection to which there was added after a time a second infection and found that here also the agglutinative powers develop in the same manner for both bacilli as is observed in the case of a single infection; occasionally there was some delay in the appearance of the second crop of agglutinins which very rarely were of but insignificant strength. Castellani then reports a few cases of mixed infection in the course of typhoid fever in which there seemed to be no disturbance in the agglutination by the serum of typhoid bacillus at the same time as special agglutinins arose for organisms of the added infection. In the case of some organisms, e. g., the colon bacillus, the blood serum may be so strongly agglutinating normally or as a consequence of the typhoid infection, that no conclusions can be drawn as the presence or absence of a mixed infection in a given case. The following procedure is suggested in doubtful cases of this kind in which it is assumed the serum agglutinates typhoid bacillus and colon bacillus: add to the serum typhoid

1. *Zeitschr. f. Hyg. u. Infektionskr.*, 1902, xl, 33-53.

2. *Ibid.*, 1-19.

bacilli in large quantities and allow the mixture to stand for some hours: if the serum now loses its agglutinative powers on the typhoid bacillus but not on the colon bacillus it probably concerns a true mixed infection. Naturally the same method is applicable to the determination of a given bacterium. It would seem that in the study just beginning, of the so-called paratyphoid infections, the question of mixed and secondary infections might be a troublesome one to clear up in some cases. Perhaps the application of the principle recommended by Castellani for the determination of the real nature of the agglutinins present might prove serviceable.

#### SANITARY CONDITIONS OF STREET CARS.

A short time ago we called attention<sup>1</sup> to some of the defects in the railroad car from a hygienic standpoint. G. A. Soper<sup>2</sup> has recently discussed the sanitary condition of street cars in New York, and what he says could be equally well applied to many larger cities in this country. The injury to health from overcrowded, poorly-ventilated quarters is well established. In such crowded apartments the effect of the foul atmosphere, which has not inaptly been called "sewer-air," is to lower the general resistance of the individual, making him more susceptible to the infectious agents which are most readily disseminated when persons come in close contact. Insufficient heat is also pointed out by Soper as injurious, both in itself and by leading to a shutting out of the outside air in order to keep warm. The matting in street cars contains an enormous number of bacteria. Sputum which is deposited in cars, after becoming dry and being pulverized by the feet of passengers, is readily disseminated through the air and then inhaled.

All of these objectionable features of street cars could be remedied by furnishing a sufficient number of properly-ventilated and heated cars to accommodate the public, and by the employment of suitable measures for insuring cleanliness and disinfection. Street railroads have adopted fenders, reliable brakes and other means of preventing direct destruction of life whenever the cost of such improvements have not exceeded the cost of the lives destroyed as measured in money value, or when they have been compelled to do so by legal enactments. Unfortunately, the injury to the health of passengers from crowded, improperly-ventilated and dirty cars can not be readily demonstrated in the individual case, and so direct claims for damages by the passengers do not act as a stimulus to the car companies to furnish better and more sanitary accommodations.

#### THE LOCALIZATION OF TUBERCULOUS INFECTION.

A tendency has grown up to look upon every infectious process as a constitutional disorder with local manifestations, whereas a little reflection will show that, as a rule, it is the opposite relation that prevails. Pathogenic agents that gain entrance into the body generally find lodgment at some point anatomically related to the channel of entry. Here, they are most likely to set up their peculiar morbid processes, from which, however, extension may take place by continuity or con-

tiguity of tissue, or through the blood or the lymph vessels. In any event the individual lesions are essentially local, although they may not be circumscribed, but rather diffuse or disseminated in distribution. Whether the one or the other, the poisonous products resulting from the reaction between the invading micro-organisms and the attacked tissues are distributed through the circulation and reach all parts of the body, thus giving rise to the constitutional phenomena. The micro-organism acts as a local irritant, while its toxin acts as do other chemical substances. It is probable, further, that both bacterium and toxin have special affinities for certain tissues by reason of which more or less characteristic—if not specific—lesions and symptoms result. The importance of the foregoing considerations resides in their bearing upon the possibility of cure and receives illustration in a recent communication by Dr. O. V. Petersen<sup>1</sup> upon the tuberculous diseases of the skin and their relation to the internal organs. He dwells especially upon the fact that tuberculosis, whether situated in the lungs or in other organs, on the skin, in the bones, in joints, is usually a local disorder, although in a small proportion of cases the process is generalized. Accordingly, he believes that in addition to increasing the resistance of the body to the carriers of infection the treatment should be principally local, as, for instance, the use of phototherapy in cases of lupus.

### Medical News.

#### ALABAMA.

**Evacuation of Prison.**—On account of the recent epidemic of pneumonia in the prison at Cealburg camp, and the exceedingly high mortality, the governor has ordered the 200 state convicts confined there to be removed to another locality.

**Cornerstone Laid.**—The cornerstone of St. Margaret's Hospital, Montgomery, was laid with appropriate ceremonies, May 20. The building is to be three stories high, and 140 by 90 feet. The temporary hospital will be ready to receive patients about June 1.

**Faculty Changes.**—At the annual meeting of the faculty of the Medical College of Alabama, Mobile, Dr. Tucker H. Frazer was elected to the chair of physiology and hygiene, vice Dr. W. B. Pape, deceased, and Dr. William R. Jackson was elected professor of surgery, vice Dr. W. T. Seales, deceased.

**Sanitarium Incorporated.**—At Birmingham a charter has been obtained for the Highland Sanitarium, the incorporators being Drs. Edward P. Riggs, Wyatt Hedlin, Cunningham Wilson and William M. Jordan. The building to be erected will be fireproof and will have accommodations for 40 patients.

#### ILLINOIS.

**Million Will Set Aside.**—At Springfield the will of Dr. John L. Million, a wealthy physician, was set aside, May 19, on the ground that he was of unsound mind.

**Hospital Cornerstone Laid.**—On May 22, the cornerstone of the new St. Anthony's Hospital at Rockford was laid with appropriate ceremony by Bishop Peter Muldoon. The hospital building will cost \$50,000 and the institution will be under the charge of the Sisters of St. Francis.

**Illinois Doctor Arrested in Missouri.**—Dr. John M. Davis, Hamilton, who has been making professional visits to different towns throughout Macon County, Mo., during the past fifteen years, was arrested recently at Macon on information filed by the prosecuting attorney of the county, charging him with practicing medicine without a certificate from the Missouri State Board of Health.

#### Chicago.

**Polish Hospital Dedicated.**—On May 25, with elaborate ceremonies, the hospital of St. Mary of Nazareth was dedi-

1. THE JOURNAL A. M. A., Feb. 8, 1902.

2. Medical News, April 19, 1902, 737.

1. Berliner Klinische Wochenschrift, April 21, 1902, p. 352.

cated by Bishop Muldoon of this diocese. The building is a fire-proof stone and brick structure 196 by 87 feet, and has cost more than \$250,000.

**Convalescent Hospital Needed.**—One of the most urgent needs of this city is a convalescent home or hospital. From Cook County Hospital alone 60 patients are discharged daily, and many of these are not sufficiently strong to be able to return to work. An institution, preferably located in the country, would be of incalculable value to these patients.

**The Hot Spell.**—The first death of the season from sun-stroke occurred during the week, and the unseasonably hot weather, although brief in duration, had a decidedly unfavorable effect on the public health, shown chiefly in an increased mortality among infants. The effect was also marked upon the quality of the milk supply, the number of samples below grade, 9.2 per cent., being double that of the week before. Three samples were found containing formalin, added to prevent souring.

**Increase of Suicide.**—Among deaths from all the different forms of violence, only in those by suicide, is there any increase during the last decade. During the eleven years, 1880-1890 inclusive, there were 1272 suicides out of the total of 7898 violent deaths—a proportion of 16 per cent.; during the eleven years, 1891-1901, there were 3681 suicides out of a total of 17,023 violent deaths—a proportion of 21 per cent. and an increase of 30 per cent. in the proportion of suicides.

**The Dispensary Question.**—Resolutions denouncing the faculty of the College of Physicians and Surgeons for establishing free dispensaries throughout the city were adopted after a heated debate at a meeting of the Alumni Association of the college, May 19. Representatives of the faculty were present and answered the charges made by the committee on resolutions. The resolutions declared that the free dispensaries encouraged pauperism and were directly in opposition to the graduates of the institution, who had settled in different parts of the city only to find that their alma mater had surrounded them with free establishments. In answer to the charges the secretary of the faculty said that the dispensaries were established for the instruction of the students of the college as well as for the good that could be done for the poorer class.

**Increased Longevity.**—The two sets of data which supplement and corroborate each other show that the average duration of life in Chicago has increased from less than fourteen years to more than thirty-one years in the last third of a century—considerably more than doubled in a single generation. They show that, exclusive of deaths by suicide, there is a decrease of 6.3 per cent. in the proportion of deaths from all other violence and of 6.7 per cent. in those from homicide or manslaughter, comparing the period between 1880-1890 with that between 1891-1901. Included in "all other violence" are the deaths from railway and street-car accidents, and these show a decrease of more than 5 per cent. in the whole of the latter period, while in the last six years, 1895-1901, during which track elevation of railways, fenders on street cars, and other measures of safeguarding life and limb have been developed, the decrease is from 21.7 per cent. of all violent deaths in the earlier period to 18.8 in the latter six-year period—a decrease of deaths from street-car and railway accidents of 12.6 per cent., or more than one-eighth.

**Influenza and Suicide.**—The relation, as cause and effect, of influenza and suicide is clearly demonstrated by a further study of the figures. The fourth great pandemic of influenza in this country began in December, 1889, since which time Chicago has never been entirely free from the infection. Influenza is a subtle and insidious malady, not usually killing outright, but fatally complicating other diseases and profoundly affecting through the toxin or poison of its bacillus the brain and nervous system, and so causing all forms of mental and nervous disturbances, from simple melancholia to suicidal mania. This disturbance may take years to develop, and it was not until 1895 that the full effects of the 100,000 cases estimated in 1890 began to be manifest. During the seven years, 1888-1894, there were 9565 violent deaths, 1677, or 17.4 per cent., being suicides; during the succeeding seven years, 1895-1901, there were 10,557 violent deaths, 2544, or 24 per cent., being suicidal, an increase of 38 per cent. in the proportion of suicides. Since January 1 of this year there have been 166 suicides, an increase of 10 per cent. over the number during the corresponding period of last year.

#### INDIANA.

**Typhoid Under Control.**—The statistics of the State Board of Health indicate that the state is getting typhoid fever under

control. There were only 1198 deaths in 1901 from the disease, as against 1320 in 1900, and about 15,000 cases, as against about 17,500 in the previous year.

**St. Edward's Hospital Staff.**—The following-named are announced as the staff of St. Edward's hospital, New Albany: President, Dr. John Hazlewood; surgical staff, Drs. Charles P. Cook, Robert W. Harris and Elihu P. Easley; medical staff, Drs. John F. Weathers, Charles W. McIntyre, William C. Windstandley and Frank H. Wilcox; gynecologists, Drs. Anna I. McKamy and George H. Cannon; medical consultants, Drs. Charles Bowman, Thomas C. Neat and Seymour C. Wilcox; surgical consultants, Drs. John H. Lemon and Edwin L. Sigmond; anesthetist, Dr. William L. Starr.

**Mortality and Morbidity in Indiana in April.**—The State Board of Health *Bulletin* reports 2716 deaths in April, an annual rate of 13.1 per 1000. In the corresponding month last year there were 2839 deaths, or an annual rate of 13.7 per 1000. In the preceding month there were 3045 deaths, an annual rate of 14.2 per 1000. By important ages the deaths were: Under 1 year, 411; 1 to 5, 170; 5 to 10, 61; 10 to 15, 76; 65 and over, 760. By important causes—pulmonary tuberculosis, 381; other forms of tuberculosis, 48; typhoid fever, 41; diphtheria, 24; scarlet fever, 12; measles, 12; whooping cough, 20; pneumonia, 352; diarrheal diseases, 22; cerebrospinal meningitis, 30; influenza, 37; puerperal septicemia, 14; cancer, 82; violence, 18. All cities, representing a population of 857,840, reported 1166 deaths, an annual rate of 16.5 per 1000. The county, representing a population of 1,658,622, reported 1550 deaths, an annual rate of 11.4 per 1000.

#### MARYLAND.

**Dr. Samuel T. Haffner,** Frederick, has been appointed health officer of Frederick County.

**New Hospital in Cambridge.**—A lot 240x240, in a desirable location in Cambridge, has been purchased for \$2500, and upon it will be erected the hospital for which \$10,000 was appropriated by the last legislature.

**Consumptive Hospital Report.**—The annual report of the Hospital for Consumption of Maryland, shows that 54 cases were treated, of which number 7 were discharged cured, 16 much improved, 16 unimproved, and 15 still under treatment. The hospital is the only one of its kind in the state. A new water system has been installed and a handsome memorial cottage erected by the daughters of one of the directors.

#### Baltimore.

**Contract Let.**—The contract for the new clinical building at the Johns Hopkins Hospital (mentioned last week) has been given out. The building will be five stories and will cost \$250,000.

**Eastern Dispensary.**—Dr. R. S. Kirke has been elected resident physician and Drs. Arthur Hedd and A. L. Tumbleson assistants at the Eastern Dispensary. During the past year 21,122 patients have been treated and 15,619 prescriptions have been compounded in the institution.

**Kerosene vs. Mosquitoes.**—As the city authorities will not do anything in the premises, Dr. Bosley, health commissioner, advises the various improvement associations to make appropriations from their funds for the purchase of coal oil and its distribution over stagnant ponds and other breeding-places for mosquitoes.

**Anthrax in Baltimore.**—A case of anthrax was recently admitted to the Franklin Square Hospital. It was that of a young woman who works in a large hair factory in the suburbs. The disease began in her upper lip, which was cauterized with fuming nitric acid. This is said to be the only case admitted to any of the hospitals here in more than 15 years.

**Personal.**—Dr. J. A. Seligman has been re-elected visiting physician to the Hebrew Hospital Dispensary for the ensuing year.—Dr. Aaron Friedenwald sailed for Europe, May 20.—Dr. William Osler has been ill with laryngitis for the past two weeks.—Dr. John H. Grimes will sail for Europe, June 21. He will spend the summer in traveling over the continent and Great Britain.—Dr. Charles E. Simon has gone to Chester, Nova Scotia, for the summer.—H. O. Reik is attending a medical convention at Los Angeles, Cal., and Dr. John N. Mackenzie a meeting in Boston.

#### MICHIGAN.

**Saginaw Valley Medical College,** Saginaw, graduated a class of 41, including three women, May 21.

**Hospital Day at Grand Rapids.**—The first "hospital day" at Grand Rapids was a pronounced success, as the receipts exceeded \$2600.

**Doctor Wins Suit.**—The \$10,000 suit of Eugene Fowler of Owosso against Dr. Charles D. Smith, Muir, was decided in the Circuit Court in favor of the defendant, May 21. The suit was for alleged malpractice in setting a broken limb, and the feature of the case was the overwhelming preponderance of expert medical testimony in favor of the defendant.

**Diphtheria in Michigan.**—The State Board of Health has issued a pamphlet relative to diphtheria in Michigan in 1900. The pamphlet embodies comparisons with previous years and includes diagrams illustrating graphically the lessening of diphtheria by isolation and disinfection, especially since the introduction of antitoxin as a curative agent and as a preventive of the disease. Before the use of antitoxin there were about five times as many cases and deaths in outbreaks in which isolation and disinfection were neglected as in outbreaks in which these measures were enforced. Since 1898, when antitoxin began to be employed as a preventive, the cases and deaths have both been lessened, but the cases per outbreak have been lessened much more than the deaths, the average cases per outbreak being greatly reduced in number.

#### NEW MEXICO.

**Hospital Burned.**—The just-completed hospital building, drug store and physician's office of the Mescalero Agency, Otero County, was recently burned. It will be rebuilt immediately.

**Hospital Addition.**—The Santa Fe-Pacific Hospital, Albuquerque, is to be doubled in capacity by a two-story addition, which is already well under way. The increased accommodation is urgently needed, as the hospital has been crowded for the last six months.

**Addition to Sanatorium.**—Work has begun on an extensive addition to St. Joseph's Sanatorium, Silver City. This institution, which was initiated only last fall, has outgrown its present quarters and the new building is a necessity. The completed building will form four sides of a square or court, in old California mission style. The building will be but one room thick and one story high, with porches outside and inside, upon which the rooms open by means of French windows. The kitchen, dining-room and research laboratory are in separate buildings. A complete hydrotherapeutic apparatus will be installed. The management of the institution is entirely in the hands of the Advisory Board. The immediate care of patients is entrusted to Dr. William T. Williams, and Dr. E. S. Bullock is the pathologist and diagnostician. The plan of treatment pursued is the careful application of the Brehmer principles, in an ideal climatic environment.

#### NEW YORK.

##### New York City.

**Dr. Joseph S. Carley** was struck by an electric car, just as he was leaving the Woman's Hospital, and received a fracture of the nose and of several ribs, and numerous painful bruises.

**Beth Israel Hospital.**—The new building of the Beth Israel Hospital, at the corner of Jefferson and Cherry streets, was dedicated with appropriate ceremonies May 25, after which the edifice was thrown open for inspection.

**New City Hospital for Consumptives.**—Commissioner of Charities Homer Folks, in his report for the first quarter, states that since the new hospital for consumptives was opened on Ward's Island on January 31, the wisdom of establishing such an institution has been amply demonstrated. During February and March, 194 patients were received, and these not hopelessly diseased at the time of admission have shown gratifying improvement.

**Fund for Study of Cancer.**—It is announced that Mrs. Collis P. Huntington has signified her willingness to create a fund of \$100,000, the interest of which may be used by the General Memorial Hospital for pathologic research into the nature of cancer. It will be recalled that originally this hospital was known as the New York Cancer Hospital, but the name being objectionable to many and the field too restricted, the present name was substituted.

**Donation to Long Island College Hospital.**—Mr. Henry W. Maxwell, formerly president of the Board of Regents of this hospital, gave during his life \$100,000 toward the erection and maintenance of a training school for nurses. He bequeathed about \$3,000,000 to his brother, Mr. J. Rogers Maxwell, who now announces his intention of giving \$400,000 for the erection of a new hospital. The new building will be lo-

cated at Henry and Amity streets, Brooklyn, and will be a modern hospital, of brick, with stone trimmings, the main structure being five stories in height, and the four pavilions being connected by glass-enclosed corridors which will be utilized as sun parlors. After the completion of the new edifice, the name of the hospital is to be changed to the Maxwell Long Island College Hospital.

#### Buffalo.

**Pathologic Section.**—Drs. Irving P. Lyon and Jacob S. Otto were elected chairman and secretary, respectively, of the Pathologic Section of the Buffalo Academy of Medicine.

**The Buffalo Society for the Prevention of Tuberculosis** is desirous of furnishing speakers to such organizations and assemblies as might be interested in the question of tuberculosis and its prevention. Under the auspices of this society, Prof. Herman M. Biggs, medical health officer of Greater New York, addressed a public meeting at the Central Presbyterian Church, May 30, on "Consumption, and How It May Be Prevented." Previous to the meeting a complimentary dinner was given for Dr. Biggs by members of the profession.

#### OHIO.

**New Clinic Hall.**—Toledo Medical College expects to build this summer a new clinical building to cost between \$5000 and \$8000.

**Increase of Salaries at State Hospitals.**—The senate has made a law increasing the maximum salaries of assistant physicians at state hospitals from \$700 to \$1200.

**Militia Medical Appointments.**—The adjutant-general has commissioned Dr. Alden V. Smith, Canton, major and surgeon, and Drs. John S. Stewart, Mansfield, and Harry B. Bertelette, Shreve, as captains and assistant surgeons, and has assigned them to the Eighth Infantry.

**Faculty Changes at the College of Physicians and Surgeons.**—At the annual meeting of the medical department of the Ohio Wesleyan University, Cleveland, a number of important changes were made in the personnel of the faculty. Dr. N. Stone Scott was made chairman of the faculty; Dr. Albert R. Baker was elected registrar in place of Dr. Henry E. Handerson, resigned; Dr. Guy B. Case was elected treasurer, vice Dr. Joseph F. Hobson, resigned, and Dr. John B. McGee was re-elected secretary.

**Personal.**—Dr. James M. McGeorge has been appointed assistant physician at the Massillon State Hospital.—Dr. Edward D. Helfrich has located in his old home, Galion.—Dr. Arthur D. Blackburn has decided to open an office in Cuba, Clinton County.—Dr. Frank H. Hurd, Dexter City, has moved to Hiram.—Dr. Carlos C. Booth, Youngstown, has resigned from the staff of the Mahoning Valley Hospital.—Dr. Asa B. Isham, Cincinnati, has been elected commander of the Loyal Legion, Commandery of Ohio.—Dr. Edward S. Wendt, Cincinnati, has been appointed an interne in Speers Hospital, Dayton, Ky.—Dr. Albert W. Binkley, Columbus, has been appointed house physician of the Deaconess' Home, Dayton.—Dr. J. Samuel Shaffer has been appointed interne at the Toledo State Hospital.—Dr. Louis A. Molony, Cincinnati, has been appointed acting assistant-surgeon in the Army and has started for California, en route for the Philippines.—Drs. Frederick C. Vogel and Walter R. Griess have started for Europe for a six months' course of study in Berlin and Vienna.—Dr. P. Maxwell Foshay has been appointed a trustee of the Ohio Hospital for Epileptics, Gallipolis.

#### PENNSYLVANIA.

##### Philadelphia.

**Reception to Dr. Rixey.**—The Medical Club of Philadelphia will give a reception in honor of Dr. Presley M. Rixey, surgeon-general, U. S. Navy, at the Art Club, June 14.

**Woman's Medical College.**—Twenty-eight students were graduated from the Woman's Medical College of Pennsylvania, May 21. The degrees were conferred by Mrs. Mary E. Mumford, president of the board of incorporators, and the graduates were addressed on the subject of "Recent Advances in Surgery," by Dr. William L. Rodman.

**Medico-Chirurgical College.**—At the annual commencement of the Medico-Chirurgical College, May 24, a class of 85 was graduated. The degrees were conferred by the president of the board, Edward M. Paxson, LL.D. Rev. John Howard Harns, Ph.D., LL.D., president of the Bucknell University, delivered the doctoreate address. On the evening of May 23, the annual alumni oration was delivered by the Hon. W. P. Potter of the Supreme Court of Pennsylvania.

**Jewish Hospital.**—At the thirty-seventh annual meeting of the Jewish Hospital Association, May 25, it was announced that the cost of maintenance of the institution for the year had been \$57,814. A bequest of \$40,000 by the late Emily Phillips, to endow the Henry M. Phillips ward, will be used in the erection of a children's hospital. Through generous gifts from Mr. and Mrs. Marx B. Loeb of Philadelphia, a new operating building will be erected and equipped. Meyer Guggenheim, of New York City, has donated \$60,000 for a new private hospital. The cornerstones for the latter two buildings, to be erected adjacent to the present hospital structures, will be laid June 1.

**Anonymous Benefactions.**—A citizen of Philadelphia, whose name is not made public, has given \$250,000 toward establishing three training schools for nurses in the South. Another has promised the gift of a farm in Alabama, valued at \$100,000, as a site for one of the schools. The project, which is said to involve the expenditure of nearly \$2,000,000, is well under way. It is under the supervision of the Philadelphia Training School for Nurses. Dr. Eugene Underhill, a member of the board of directors of this school has, with others, started South, with the view of obtaining the coöperation of leading medical schools, especially in South Carolina, Georgia and Alabama.

#### GENERAL.

**Personal.**—Dr. William H. Bleck, of Manzanillo, Cuba, is on a visit to his home in Baltimore, Md.

**Cholera in the Philippines,** by dispatches on May 27, had reached the total of 6166 cases and 3813 deaths, of which 1165 cases and 935 deaths were in Manila. One officer has died, the first victim among the officers. Among the Americans to date there have been 25 cases and 20 deaths, while among the Europeans there have been 13 cases and 10 deaths.

**Complimentary Dinner to Surgeon-General Sternberg.**—A committee of physicians, who feel that the retirement of Dr. Sternberg from the Army should not be allowed to pass without an expression on the part of his many friends of their appreciation of his long and faithful services to the country and to our profession, will, in recognition of his long-continued, varied and important scientific and professional labors and of his high personal character, tender him a dinner at New York City, June 13.

#### Smallpox.

**Illinois:** Of the 13 new cases of smallpox discovered in Chicago during the week ended May 24, the same enormous proportion of colored, heretofore noted, obtained—8 out of the total. None had ever been vaccinated—another illustration of avoidable sickness and probable death "through one's own acts" of omission.—Aurora has 21 cases of smallpox, all mild.

**Indiana:** Smallpox was the most prevalent disease during April. There were 878 cases reported in 55 counties, and 6 deaths.—The Board of Health of Gas City has issued a proclamation of free vaccination.—The secretary of the State Board of Health, after noting the fact of the presence of more than 800 cases of smallpox in the state, says: "It is my candid opinion that there were over 1,500 cases and very little effort is being made to stop it. Smallpox is costing the state of Indiana thousands of dollars every day through no fault of the officials. It can be controlled absolutely by vaccination if everybody gets vaccinated."

**Minnesota:** St. Bonifacius has 40 cases and Minnetristka township, near Lake Minnetonka, 30 cases.

**Canada:** In Simcoe County, between 30 and 40 suspected cases are reported; 3 new cases have developed at Huntsville and a new outbreak is said to have occurred in Cayuga Township, Haldmand County.

**Alaska:** Within thirteen months 2000 natives along the coast of Alaska have been vaccinated as a preventive of smallpox by the surgeon of the revenue cutter *Rush*, and it is believed that the prompt action and the thoroughness with which the duty was performed had the effect of keeping that scourge out of Southeastern Alaska. With the exception of a few cases on Ikooniah Island, the disease has not made its appearance, though the previous year it raged with great severity among the natives along the coast for a thousand miles. The *Rush* will continue the vaccination of the natives during the coming season, for which purpose more than 1000 vaccine points have been shipped to her at Sika.

The Kentucky State Board of Health, at a meeting at Louisville, May 27, quarantined against the whole state of Indiana on account of a dangerous smallpox outbreak, said to be raging in sixty of the ninety-two counties of that state. Governor

Durbin of Indiana refused to act, and as a consequence Kentucky will prevent persons coming from the north entering the state without having a certificate signed by the Indiana State Board of Health.

#### CANADA.

**Appointment.**—Dr. Wyatt Johnson, assistant professor of hygiene in the medical department of McGill University, is to be appointed professor of hygiene in succession to Dr. Craik, who a short time ago retired from the office of dean of the department.

**A Canadian F.R.S.**—Dr. Bovey, dean of the Faculty of Applied Science at McGill University, has been made a Fellow of the Royal Society of Great Britain. Dr. Bovey has been dean of that faculty ever since its foundation in 1878, and has had much to do with bringing it to its present famous position.

**Coronation Contingent Must Be Vaccinated.**—Every officer and man selected for the Canadian Contingent for King Edward's coronation will have to provide himself before leaving his place of residence with a certificate from a militia medical officer to the effect that he has good vaccination marks, or that he has been recently vaccinated or has had smallpox.

**Arranging Hospital Patients According to Religious Belief.**—According to the most recent action of the Montreal City Council in regard to the construction of the proposed civic hospital for contagious diseases, the patients will be cared for according to their religious beliefs. The hospital is to be built on the pavilion plan, the pavilions to be so arranged and the nursing staff so divided that the Catholics will be entirely separated from the Protestants.

**Medical Item from Labrador.**—Dr. Wilfrid Grenfell, the English physician who is devoting his life to the fisherfolk of Labrador, writing to a friend in Montreal, states that there is great destitution among the inhabitants of that country. The work of this medical practitioner ranges from treating a compound fracture to making a pair of boots from the skin of a freshly skinned seal. He has recently had completed the third hospital, viz., that at St. Anthony on the north French shore.

**Proposed New By-Law on Vaccination in Montreal.**—Another by-law re vaccination will shortly be submitted to the city fathers of Montreal, the one for compulsory vaccination having been rejected by a considerable majority. The new one will provide that vaccination must be performed by duly qualified physicians only, and that proper aseptic methods be employed. The object of this will be to prevent the untoward after-effects from the operation, which seem to have been very prevalent in Montreal during the past outbreak of smallpox and which have had a good deal to do with the neglect of vaccination by the people.

**Consumption Sanatorium Burned.**—Early on the morning of May 21 the Laurentian Sanatorium at St. Agathe des Monts, about fifty miles from Montreal, was totally destroyed by fire, one woman being consumed by the flames. The sanatorium, owned by Dr. Arthur J. Richer of Montreal, was opened by him about five years ago, and has been doing good work for consumptives in the province of Quebec, being the only institution of its kind in that province. At the time of the fire fifteen patients were undergoing treatment under the supervision of Dr. J. A. Ferguson. As soon as the alarm of fire was given this medical officer, regardless of his own danger, alarmed the inmates and had them conducted and carried to places of safety with one single exception. The sanatorium had accommodation for twenty patients and had a competent staff of nurses. The loss will be in the neighborhood of \$15,000.

#### FOREIGN.

**Free Midwifery.**—The canton of Tessin in Switzerland has recently passed a law providing for the payment by the state of the fees of midwives.

**Reduction of Rates on German Railroads for Persons Traveling to Hospitals or Sanatoria.**—The German authorities now grant half fares to members of the sick insurance societies traveling to or from a sanatorium on medical advice; also to poor persons provided with a medical and local certificate as to their destination and poverty.

**Two Dollars the Legal Fee in Paris.**—A recent legal decision states that ten francs—equal to \$1.93—is the customary fee in Paris for the visit of a physician to persons in the medium station of life. The statement was made in a judgment against a physician who had presented her bill at the rate of 20 francs for the first visit and 10 for each subsequent visit.

**Deaths Abroad.**—Our exchanges report the death of the Berlin professor of ear diseases, Dr. F. Trautmann, Geheimrath

Medicinal Bath; of Dr. Römpler, the founder of the celebrated sanatorium for lung diseases at Görbersdorf; Dr. Beely of Berlin, prominent in orthopedic surgery; the professor of surgery at Naples, Dr. Frusei; Dr. Möller of Copenhagen; the professor of physiology at Strassburg, Dr. F. L. Goltz; and Dr. Kalindero, professor of medicine at Bucharest.

#### Instruction in Anatomy for Women Medical Students.

—The German Congress of Anatomy met at Halle, April 22, with a numerous attendance from all the countries of continental Europe. The instruction of women medical students in anatomy was one of the subjects discussed. These professors who have had most experience in this line were unanimous in favor of separate medical instruction for women, although the women themselves do not wish it.

**The Schweninger Affair.**—The fine large district hospital of Gross Lichterfeld near Berlin was placed in charge of Schweninger, Bisnarek's medical attendant, a man of no scientific qualifications but with considerable political influence. In his administration of the hospital he is said to have ignored the fundamental principles of modern medical and surgical science, and von Bergmann has finally been appointed on a committee to investigate the complaints. He has succeeded in securing the appointment of his former assistant, Dr. H. Stabel, to the position of surgeon in chief to the hospital, to work side by side with Schweninger and enforce modern scientific methods, in spite of his opposition.

**Reciprocity in the Privileges of Physicians.**—The Italian physicians have been appealing to the government to forbid the practice of medicine in Italy to foreign physicians whose home countries do not allow similar privileges to resident Italian medical men. After considerable discussion the request has been refused, the authorities stating that legislation of this nature would be a step backward, and that foreign physicians are the most effective advertisers of Italy as a health resort. It is interesting to note that almost simultaneously the authorities of Cape Colony have issued a regulation taking this very step, forbidding the practice of medicine in the colony to physicians from countries in which reciprocity is not the rule. Cape Colony is one of the few countries in which there is a scarcity of medical men.

#### LONDON LETTER.

##### Decrease of Smallpox Continues.

The number of cases in hospital is 1419 against 1431, 1515 and 1442 in the three preceding weeks; during the week 248 new cases were admitted, against 328, 367 and 250 in the three preceding weeks.

##### Bovine and Human Tuberculosis.

At the last monthly meeting of the Council of the Royal Agricultural Society of England, Sir Nigel King-cote presented a report of a subcommittee appointed to supervise experiments conducted at the Royal Veterinary College as to the possibility of infecting bovine animals with tuberculous material obtained from the human subject. The experiments were performed on a cow, two young calves and two yearlings. The virus was injected into the udder of the cow, was given to the calves by the mouth and was injected into the veins of the yearlings. The possibility of infecting cattle with human tubercle bacilli was proved. The bacilli had multiplied in the body of the cow and produced a manifestly diseased condition. In the other animals distinct evidence of tuberculosis could not be found after they were killed, but during life they reacted to tuberculin. This was held to indicate that the infection was of a temporary nature. Taking all the facts into account the experiments were held to show that the risk of infection to cattle from man was slight, but no conclusion as to the converse risk could be drawn.

##### Cyto-Diagnosis of Pleural Effusions.

At the Edinburgh Medico-Chirurgical Society, Dr. G. L. Gulland read an important paper on this subject. He said that in several kinds of pleural effusion, for example, in empyema, examination of the cells was unnecessary, the pathogenic organisms alone being important. In serous effusions, however, the cells were of importance. For many years it had been discussed whether common acute serous pleurisy was tuberculous, rheumatic, "idiopathic," or due to infection. All ordinary means of diagnosis might be exhausted without deciding the nature of the case. The case might be tuberculous, and the effusion might conceal pulmonary disease. The injection of tuberculin was almost useless for pyrexia was usually present. The sero-diagnosis of tubercle offered so many practical and other difficulties that for practical and other purposes it was

useless. In the fresh pleural exudate organisms might be discovered by culture or by the microscope, but the fluid was strongly bactericidal, and after some time the organisms ceased to be capable of cultivation, though they might be found in the fluid. In undoubtedly tuberculous cases tubercle bacilli could be demonstrated only very rarely, either because few bacilli were present, because they were destroyed or rendered incapable of growth by the fluid, or because the effusion was due to toxins rather than the organism itself. To examine the cells of the exudate enough fluid should be obtained with a sterilized syringe to enable it to be centrifuged. If the cells in the effusion were numerous, cover-glass preparations might be directly made. For staining eosin, methylene blue and Jenner's stain were useful. To show granules in polymorphonuclear cells or other changes Sudan, followed by hematoxylin when fat was in question or iodine when glycogen was, had to be used. In established tuberculous pleurisy the microscope showed lymphocytes, erythrocytes, and in some cases a few polymorphs and very few endothelial cells. The lymphocytes ought to be at least half the true cellular elements, while in some cases they were four-fifths or even more. The serous stage of pneumococcal and streptococcal pleurisy and probably of all pyogenic organisms gave the same results—great preponderance of polymorphonuclears, unaltered or degenerated, as the case may be, and often numerous endothelial cells, fresh or degenerated. Erythrocytes might also be present. The relation between the polymorphs and endothelial cells varied greatly in different cases; the more acute the case and the more likely to go on to empyema the more polymorphs as a rule. In edematous effusions, whether from renal or cardiac disease, the cells were few and mainly endothelial. In malignant pleurisy, cells of the growth were present in the fluid, often in large numbers. They were frequently swollen and edematous, and presented abnormalities of the nucleus and fatty degeneration. A certain proportion of the polymorphs were present. Dr. Gulland has found cyto-diagnosis distinctly useful, particularly in deciding the question of tuberculosis.

#### The Morphia Habit Case: Dr. Law's Expenses To Be Defrayed by Subscription.

This case, in which a nurse unsuccessfully sued her physician because she became addicted to morphia after his prescribing it for her, has been described in THE JOURNAL. At a meeting of doctors called to express sympathy it was stated that Dr. Law's expenses amounted to \$3500. Subscriptions amounting to \$1800 have already been received from all parts of the United Kingdom and from all classes of the profession. The presidents of the Royal College of Physicians, of Surgeons, the master of the Apothecaries' Society and the editors of the metropolitan medical journals have been requested to act as trustees of the fund for the payment of Dr. Law's expenses.

#### Physical Deterioration of the Population of Towns.

The recruiting returns for Manchester show in a striking manner that the deterioration in physique of the population of towns which has been frequently asserted is not a produce of alarmist exaggeration. Some three years ago it was found that of 11,000 men examined only 3000 were fit for service. In 1900, of 12,235 applicants only 4030 were fit to serve. In 1901, 11,896 men were examined, of whom only 3076 were accepted. Those rejected were for the most part so ill-developed and poor in physique that it was impossible to take them, though the authorities were anxious to accept as many as possible. The standard is now lower than it has ever been. A minimum chest measurement at full expansion of 33½ in. and a minimum height of 5 ft. 3 in. are sufficient. Many Manchester applicants for enlistment are youths of 18 or 19, average specimens of those living in the poorer parts of the city. The chest measurement is often only 28 or 29 in. and they are undersized in proportion. The recruiting officers think that the principal cause of this want of physique is the habit of cigarette smoking by youths. They come with their fingers stained by cigarettes and nearly all suffer more or less from palpitation of the heart. But this is obviously only one factor of many. These youths are born in the vitiated atmosphere of a town slum, are unsuitably fed as infants, and are brought up in ill-ventilated tenements.

#### Arsenic and the Increase of Cancer.

To explain the increase of cancer in this country, of which statistics have recently been given in THE JOURNAL, Mr. Jonathan Hutchinson in the *Polytechnic* advocates a very daring and characteristically original hypothesis. Many years ago he made the remarkable discovery that the prolonged use of arsenic gives rise to horny growths (corns) on the palms and

soles which in certain cases terminate in cancer. This observation, at first received with incredulity, has been amply confirmed. It may be remembered that the evidence given before the Royal Commission, which has been published in *THE JOURNAL*, shows that in addition to the contaminated sugar which was the cause of the epidemic of arsenical poisoning in the North of England and the Midlands there was another source of arsenic in beer—the coke used to dry the malt. The quantity of arsenic derived from this source is, however, very minute. Mr. Hutchinson points out that it is precisely during the period in which coke has taken the place of wood in drying malt that cancer has increased. During this period no doubt a number of cases registered as “peripheral neuritis,” “vagabond’s melasma,” “pernicious anemia” and “multiple cancer of the skin” were due to arsenic. But if the continuous use of arsenic in small medicinal doses can predispose to cancer of the skin there is no good reason for doubting that it may do the same for cancer for other tissues. Probably it is a contributory rather than an efficient cause. There must also be the constitutional tendency, the appropriate age, and in some cases local irritation.

#### Cancer Research.

The importance of the cancer problem has been well brought before the public and the claims for assistance in research are receiving good response. The latest example of munificence is that of a Dundee manufacturer who has offered to the directors of the Dundee Infirmary \$90,000 to erect a cancer hospital containing six wards capable of accommodating 16 to 20 patients and a ward for private patients. He has also offered to guarantee \$5000 a year for 5 years for a laboratory for original work in investigation.

### Correspondence.

#### Medical Education for Women.

CHICAGO, May 22, 1902.

*To the Editor:*—Your editorial on medical education of women in *THE JOURNAL*, May 17, is evidently written as a friend, but, I fear, a misguided one. You advocate a special curriculum for women, claiming that their peculiar psychophysical status is not met under the present conditions. You wish to exclude major surgery, on the ground that women lack the courage and quick judgment necessary for this work. Is this true? Any one acquainted with the work of medical women knows better. The matter of adaptation of women to major surgery is a matter of individuality, just as it is with men. There are men who faint at the sight of blood and there are women who can do major surgery. I have seen the late Dr. Marie J. Mergler perform a double ovariectomy, through the abdominal route, in a case of sarcoma of the ovaries, each weighing from 5 to 10 pounds. There was extreme ascites, causing dangerous dyspnea in the case, and the patient was in a grave cachectic state. The operator exhibited as much self-possession, courage and good judgment as could be desired in any surgeon, man or woman. The patient made an uneventful recovery. Our cry is “More surgery!” We want just as broad and generous a course as we can get, for we have to work against all odds, having to contend with prejudice against us of the laity, and, I regret to say, some of the profession.

You consider obstetrics the future field of women in medicine. Is it because it is better adapted to the lower physical standard of women? We all know that the art of obstetrics is about as hard a branch of the practice of medicine as there is. It is full of surprises and comparatively poorly remunerated. Does not a pedicle version, a symphysiotomy or a Cesarean section require quick judgment and dauntless courage, when we consider that there are two lives at stake? And what about forceps delivery?

You also claim that women prefer men accoucheurs because of the stronger judgment of men and the better advantages they have in obtaining obstetric experience. This is neither true nor fair. Women practitioners, especially those who had the advantage of an interne’s service in a woman’s hospital, are better prepared for obstetrics than many a man. Obstetrics opens to us many a home, and we are later employed as

family physicians. I quite agree with you that women make better pediatricians and that there should be more women in eye, ear, nose and throat work. It will come with increasing hospital facilities for women to specialize.

“Psychology proves,” you continue, “that woman’s discriminating power and accuracy of movement are inferior to those of men. Perhaps this demonstrated fact explains all these doubts concerning feminine surgery of every sort.” But, my dear Doctor, why can not a woman tie a ligature or put in a suture as well as a man? Is it because with her nimble fingers she has been handling the needle and thread in making garments ever since the birth of the race? Read the article in the last issue of the *Woman’s Med. Journal*, on “Women in Medicine in Russia,” and you will see what women can do even on the battlefield.

At last, we are getting to the climax of this very valuable editorial. “However, the whole question of woman’s place in medicine hinges on the fact that when a critical case demands independent action and fearless judgment, man’s success depends on his virile courage, which the normal woman has not, nor is expected to have.” It is over 35 years since women have first invaded the field of medicine. England, France, Russia, Switzerland, the United States, and lately Germany, have opened the doors of medical schools to women on par with men. Women have demonstrated their ability as students and practitioners and their field of work is growing in scope with every year. Woman in medicine is no longer an experiment. She has come to stay. What we want is a high standard of preliminary as well as of professional training. More surgery, more medicine, more pathology, more bacteriology, etc., more of everything that makes a good doctor. We claim the rights of the individual. There are strong and able—yet normal—women and weak and incapable men.

#### Young’s Modification of My Prostatic Incisor.

BERLIN, GERMANY.

*To the Editor:*—In *THE JOURNAL* of Jan. 11, 1902, Young described a modification of my prostatic incisor under the title of “A New Combined Electro-Cautery Incisor for the Bottini Operation for Prostatic Obstruction.” According to him the chief advantage of this modification is, that knives of different heights may be used. Young believes to have brought out something new by this, but he is mistaken.

As proof of the above statement, I quote the following from my article of January-February, 1900, entitled: “Neue Mittheilungen zur Galvanokaustischen Radikalbehandlung der Prostatahypertrophie per vias naturales (Bottini’sche Operation).”<sup>22</sup>

“Die Tiefe der Schnitte scheint *theoretisch* gegeben durch die Höhe des—bekanntlich messerförmigen—Kauters, gemessen senkrecht zum Schaft. Es muss danach, da die Höhe des als Beispiel gewählten mittleren Lappens eine verschiedene sein kann, zweckmässig erscheinen. Messer von verschiedener Höhe zur Verfügung zu haben. In der That habe ich mir deswegen auch für meinen Gebrauch Incisoren mit verschiedener Höhe des galvano-kaustischen Messers—von 0.8, 1.0, 1.2 und 1.4 bis 1.5 cm. Höhe—anfertigen lassen und treffe zwischen diesen, je nach dem kystoskopischen und dem hierfür noch wichtigeren, *Rektalbefund bei liegendem und nach hinten gewendetem Instrument* eventuell meine Auswahl.”

[English translation<sup>3</sup>: “*Theoretically* the depth of the incision is represented by the height of the galvanocaustic knife, measured from its tip to the shaft at a right angle. It would seem, therefore, taking as an example the middle lobe, which may vary in size, to be an advantage, to have knives of different heights at our disposal. For this reason I had galvanocaustic knives made for me, measuring from 0.8, 1.0, 1.2 and 1.4 to 1.5 cm. I choose one of these, according to the cystoscopic finding, and, what is still more important, the *rectal*

3. Translated by Otto M. Schwerdtfeger, M.D., New York.

*finding taken after the instrument has been introduced and turned backward."*

I added the following note at the time (Foot-note No. 17):  
 "Als Durchschnitt lasse ich die Instrumente mit Messer von 1.2 cm. Höhe anfertigen, das jedenfalls die am meisten zu verwendende Messerhöhe darstellt, 0.8 cm. scheint mir entbehrlich, 1.4 bis 1.5 cm. ist für viele Fälle zu hoch und schon deswegen leicht bedenklich, weil naturgemäss mit einer grösseren Höhe des Messers auch die Neigung zu eventueller Verbiegung steigt. Dass man übrigens einen Schnitt auch dadurch weiter vertiefen kann, dass man—in derselben Sitzung oder in einer späteren—noch einmal in dieser Richtung schneidet, braucht nur erwähnt zu werden."

[English translation: "As a rule, my instruments are manufactured with a knife of 1.2 cm., which represents the height mostly used, 0.8 cm. seems to me to be dispensable; 1.4 to 1.5 cm. is too high for many cases and has this further disadvantage, that the tendency to bend is naturally greater because of the increased height. It need only to be mentioned that the incision can be deepened by recutting in the incision either during the same sitting or at a later one."]

I treated on the same question in my article<sup>4</sup> on "The Treatment of Hypertrophy of the Prostate Gland by the Galvano-caustic Method after Bottini," in W. H. King's "Electricity in Medicine and Surgery." It may be found on p. 206, and is as follows:

"The depth of the incision is dependent, on the one hand, on the fact that the instrument be firmly pressed upon the prostate gland; on the other hand, on the height of the knife. I possess knives of various sizes, from 0.8 to 1.5 cm. in height and choose between them dependent on the thickness of the prostate gland. As an average size 1.2 cm. is to be designated; my instruments are supplied with this size unless another size is especially ordered. The incision may also be deepened if the instrument is firmly pressed down and the knife is moved to and fro for a second time, along the furrow. In general, however, this is not expedient."

To be sure, I did not have an entirely new instrument made for each different knife: with my instrument, different male parts alone are necessary, the female remaining the same. The only difference between this and Young's is, that in his, a part of the outer end of the male portion remains the same. It is a question if there is any advantage in his arrangement, because the expensive part of the instrument is the platinum-iridium knife, of which one must have several in either case. The disadvantage of Young's is that the male part is made up of two pieces whereby it suffers in simplicity and safety.

In addition, I wish to emphasize that, as my experience increases, I have become convinced that knives of different heights are not of the great significance which I formerly thought, but one averaging 1.2 to 1.3 cm. in height is sufficient for all cases.

I may be allowed, as substantiation of this, to state that in my last 37 cases, as far as I can remember, all—or, at least, nearly all—were operated with a knife of 1.2 cm. height and in these 37 cases (excepting one death, one non-success in a case with a small prostate, and one case which was operated too recently to allow of any opinion on the result) there were 34 successful results, 27 cases being cured and 7 decidedly improved.

At all events, from the above given quotations it is shown that the instrument recommended by Young can not be designated as "A New Electro-Cautery Incisor," but at most as a modification of mine. I must add that Young himself, in a letter to me, correctly recognizes this. He writes (March 24, 1902): "The instrument in question is merely a modification of your own splendid instrument."

## Inefficiency of Self-Constituted Midwives.

BERLIN, WIS., May 16, 1902.

To the Editor:—I enclose an outline of a little of my experience; if proper to print in our valuable JOURNAL it is at your service.

The testimony presented to the coroner's jury summoned by Justice Biggart to investigate the cause of death of Mrs. John Secora, who died in child-bed, May 12, showed she flowed to death and that the midwife rendered no assistance. Neither was she fitted by medical knowledge to give assistance in such cases.

The above clipping is from our local paper.

I trust it may seem time to most of us to call a halt, as far as possible, in this matter, as many like instances occur in every large community, due to the inefficiency of self-constituted midwives.

Being summoned, at the last moment, to attend the above case, I found the woman dead. She might have been buried and little thought given to the disastrous consequences overtaking nine little children, but, acting on some thoughts advanced at our last Wisconsin state medical meeting, I asked for an inquest from the head of our local board.

The evidence showed the bed badly saturated with blood, the head of deceased had not even been lowered, nor foot of bed raised, no uterine or heart stimulants given, placenta allowed to remain loose in the uterus, and only slightly attached to its walls, as postmortem revealed; everything was left in a bad state. Yet this midwife has been depended on for years, by a large Polish element in this vicinity, to attend many of them in confinement. We frequently hear it said, "If there be nothing the matter, she is as good as any doctor." How absurd!

It is proper to remark that our mayor promptly ordered the inquest, and the pretended midwife was made to realize her unfitness for these duties. There is no probability that she will again place herself where the court may be likely to demand her presence for such shortcomings. Is not this a fitting way for shutting off such uninstructed officiousness?

This community was very much stirred up over this matter when the facts were brought out. It would have passed comparatively unnoticed without the inquest. Why should this not be the rule?  
 B. F. DODSON, M.D.

## Saratoga Meetings.

Among the meetings to be held at Saratoga Springs during the week of the Association meeting are those mentioned below. Others have received previous notice in these columns.

**United States Pension Examiners of the State of New York.**—It is announced that the pension examiners of New York will meet at Saratoga Springs, on June 9, at 10 a. m. A brief literary program has been arranged, the principal feature of which will be an address by Medical Referee Raub of Washington, D. C., on "Defects in Reports of Examining Surgeons, with Suggestions for Their Improvement." A very cordial invitation is extended to every pension board in all of the New England and Eastern States to be present at this meeting. While the meeting has been called to consider the advisability of effecting an organization in New York State, it may also prove a favorable occasion on which to organize on a larger plan, so as to include all of the states above mentioned. It is to be hoped that each board will send at least one representative.

**American Medical Temperance Association.**—The eleventh annual meeting of this association will be held in the parlors of the United States Hotel, Saratoga Springs, N. Y., June 11 and 12, at 9 a. m. The president, Dr. N. S. Davis, Chicago, will deliver the annual address on "The Relations of Alcohol to the Economic, Sanitary and Moral Interest of the Human Family and the True Principles of Legislation Which Should Govern Their Use." The vice-president, Dr. Henry D. Didama, Syracuse, N. Y., will deliver an address on "The Use of Alcohol as a Predisposing and Excitant of Disease and Crime." The third address will be delivered by the second vice-president, Dr. Dudley S. Reynolds, Louisville, Ky., on "The Tobacco Habit as We See It Daily." Other papers will be read by Dr. John H. Kellogg, Battle Creek, Mich., on "The Injurious Effects of Al-

coholic Medication as Shown by Recent Experimental Observations;" Dr. Lewis D. Mason, Brooklyn, N. Y., on "Alcoholic Anesthesia;" Dr. John W. Long, Salisbury, N. C., on "Popular Delusions Concerning the Physiologic Effects of Alcohol;" Dr. John M. French, Milford, Mass., on "A Critical Analysis of the Prescription of Whisky and Strychnin;" Dr. David Paulson, Chicago, on "The Relation between Alcoholic Medication and Drug Addiction;" Dr. Charles H. Shepard, Brooklyn, N. Y., on "Auto-Intoxications from Alcohol;" Dr. Thomas D. Crothers, Hartford, Conn., on "Nerve Injuries Traceable to Alcohol Given as a Medicine," and Dr. N. Roe Bradner, Philadelphia, on "Proprietary Drugs Containing Alcohol." Several papers have been promised from Drs. Fewes, Hall, Comstock and others. The meeting promises to be one of unusual interest. The object of this association is to promote more accurate investigation concerning the action of alcohol in health and disease, and seek to disseminate the most authoritative and well-established facts, as seen from laboratory and bedside experience. A cordial invitation is given to all who are interested to attend this meeting at Saratoga. The secretary, Dr. T. D. Crothers, Hartford, Conn., will be pleased to correspond with anyone on this subject and to send circulars of its work.

**The National Confederation of State Medical Examining and Licensing Boards** will hold its twelfth annual meeting in the hall of the Y. M. C. A., Saratoga Springs, N. Y., Monday, June 9, 1902, at 9:30 a. m. and 2:30 p. m. Members and ex-members of state medical examining boards, physicians and educators who are interested in the cause of higher medical education are cordially invited to attend. Every state or territorial board whose duty it is to examine or license physicians intending to practice in the jurisdiction of the board is urged to affiliate with the National Confederation, if it has not already done so. The program is as follows:

Address of welcome, Mr. A. P. Knapp, President of Saratoga Springs.

Address of welcome on behalf of the medical profession of Saratoga Springs, George T. Church.

Address of welcome on behalf of the Regents of the University of the State of New York, Albert Vander Veer, Ph.D., M.D., Albany.

Address of welcome on behalf of the State Board of Medical Examiners of New York, William Warren Potter, Buffalo.

Response, by Vice-President Henry Beates, Jr.

Report of the Secretary-Treasurer, A. Walter Sulter, Herkimer, N. Y.

Annual address by the President: Uniformity in Medical Practice Acts, N. R. Coleman, Columbus, Ohio.

The Work of the Regents of the University of the State of New York, James Russell Parsons, Jr., M.A., Secretary of the University.

Divided Examinations for License, Joseph H. Raymond, President of the Medical Council of New York.

Discussion, to be opened by the following members: E. B. Harvey, Boston; E. L. B. Godfrey, Camden, N. J.

What Can Be Done to Regulate the Number of Young Men Studying Medicine? R. S. Martin, Stuart, Va.

The Results of the Medical Law of Tennessee, T. J. Happel, Trenton, Tenn.

Should There Be the Same Examinations for Old Practitioners and for Recent Graduates When Applying for License to Practice Medicine? Maurice J. Lewi, New York.

The Definition of the Practice of Medicine in Medical Practice Acts, Harold N. Moyer, Chicago.

How May the Topics in Examinations for License Be Best Arranged by Examining Boards? Henry Beates, Jr., Philadelphia.

Discussion, to be opened by the following members: William A. Spurgeon, Muncie, Ind.; Gardner T. Swarts, Providence, R. I.

## Miscellany.

**Children with Three Legs.**—Medical journals are mentioning two recently-reported cases of children with three legs. In one, a girl, the third leg grows from the waist and its weight makes locomotion difficult. The other case was accustomed to rest on three feet like a tripod.

**Carcinoma and Malaria.**—A recent article in the *Cbl. f. Allg. Gesundheit* gives charts showing the mortality from malignant neoplasms and from malaria in Italy. The former is largest in Tuscany and vicinity, while the latter is largest in the southern provinces. The mortality from malaria is therefore highest in the provinces in which the mortality from cancer is lowest, and vice versa.

**Perforated Tubes for Intubation.**—Some of the disadvantages of intubation are obviated by making a double row of small holes near the center and below. Suffocation is less liable to occur, as the air can pass through these holes

even if the tube is obstructed below. The air passing through them also prevents the accumulation of mucus and membranes on the tubes. It is also less liable to be coughed out. These statements made by Dionisi of Turin have been confirmed by his experience with thirty patients using these perforated tubes.

**Making Vaccination Fashionable.**—Even in medical matters the best method of making progress is to convince people that the desirable thing is popular. To make a good act fashionable it is only necessary to make others think it is fashionable. In London, despite the steady increase of smallpox and all that the profession could do to make people vaccinate, there was an invincible apathy upon the part of the public. Suddenly some member of the stock exchange introduced the practice of wearing a red ribbon about the vaccinated arm as a warning to others not to jostle. At once the custom spread and "a thousand ribboned arms may be met in five minutes anywhere in the city."—*Amer. Medicine*.

**A plan for uniformity in state medical organizations** has been proposed by the committee of the American Medical Association, composed of Dr. McCormack, Dr. Foshay and Dr. Simmons, and their report is published in the *Association Journal* of May 3. Without interfering with the proper independence of the individual state societies, their just rights as to conditions of membership, etc., the outline of the constitution and by-laws offered by the committee seems most admirable, and we hope it may be accepted, at least in essentials, by all the states of the Union. In this way may be reached that unity of the entire American medical profession by which alone we can lessen the degrading influence of quackery and aid in the making and execution of laws in a thousand ways affecting the public health. All progressive physicians should do their utmost to carry into execution the recommendations of Drs. Reed, McCormack, Foshay, and Simmons, who have labored so earnestly and nobly in the cause of professional unity and uplifting.—*American Medicine*.

**The Profits of a Medical Journal.**—The *Münchener medizinische Wochenschrift* is, it is said, owned and published by eleven physicians. Last year profits amounting to 4400 marks were divided among professional aid societies. This year the amount was 9300 marks, 5000 of which was given to the Pettenkofer Memorial Building Fund, and the balance to various societies for the relief of widows and orphans of physicians. Of those who are strangely indifferent to the imperative duty of the profession to own and control its professional journals, we would ask if they see no significance in this fact. Is it good policy or good morals for American physicians to support several hundred medical journals which, because of their number and nonprofessional control, are powerless for good, or powerful only for evil, instead of lifting the few needed to positions of honor and beneficence? There is all the difference in the world between a medical journal published in the interest of the profession and one published in the personal interests of the publisher or editor. It lies wholly in the choice of American physicians whether the policy and the profits of their journals shall be under the control of professional or of selfish motives. The splendid work that might be done by a few professionally-owned journals for the reform of hundreds of abuses, and the furtherance of medical progress should lead every one to subscribe for and contribute to those journals that by reason of their professional ownership and management can not be used for commercial or personal purposes.—*Amer. Medicine*.

**Physicians Should Furnish Abstracts of Their Papers.**—There is no one capable of doing it so well, and none is so interested in having it done correctly. The writer knows best what is the essential thing in his article and just what needs to be emphasized. Reporters, even the very best, can not possibly know and do the work so perfectly, and especially during the *viva voce* reading. The succinct short epitome in 100 or at most 200 words should be appended to the paper so that editors after its publication may use this instead of the imperfect one each would be compelled to make for his readers. When going to a medical society this abstract should be mani-

folded and as many separate slips taken as may be desired by the secretary and the medical stenographers present. By following this plan the reports in medical journals would be more concise and accurate, and every contributor would know that he is correctly reported, and that his bit of experience has been surely and exactly added to the great body of medical truth.—*American Medicine*.

**Charaka-Samhita.**—THE JOURNAL has mentioned before the translation of the ancient Hindu treatise of medicine which is being published by A. C. Kavaratna at Calcutta. The twenty-fifth and sixth parts have just been received and show that many advanced ideas in hygiene and psychology were promulgated almost coeval with Hippocrates. Those interested in tracing the history of medicine will enjoy this work in its quaint English setting. Charaka says in one place: "Blood is nourished by blood, marrow by marrow, semen by semen and conception is favored by eating the raw fetus of some animal. In case the same substances are unattainable, administer those possessed of the same attributes, for example, in case of anuria give sweet or acid or saline articles and all endowed with laxative properties. For absence of bile, give acid, saline or pungent, articles or alkaline, heating or keen." He enjoins "indulgence with deliberation in all such acts as sleeping, eating, seeing, sporting, moving of limbs." He observes: "It is one thing to have good food and another thing to digest the food one has." About 800 pages have been published to date. The translator is the editor of the *Bengali Medical Journal* and announces that he is a practitioner of the Hindu System of Medicine. His footnotes are not the least interesting part of the work, almost surpassing the parts devoted to anatomy and embryology.

## State Boards of Registration.

**The Maryland State Board** examinations will be held in Baltimore June 11-14.

**Mississippi Physicians**, to the number of 73, were added to the list of that state's licensed practitioners, out of 153 applicants for the coveted permission.

**Manitoba Examinations.**—Candidates for license to practice medicine in Manitoba met, to the number of 113, at Winnipeg, May 12, for several days' examination.

**The Cherokee National Medical Board** for the Central District of the Cherokee Nation will be in session at Tahlequah on June 5 to examine physicians and surgeons desiring to practice.

**In Louisiana**, May 1 and 2, 65 applicants presented themselves for license by the State Board of Medical Examiners, 57 passed and 8 failed; 4 applicants were colored and 3 failed. There were 7 applicants for license to practice midwifery, 4 of whom were colored; 2 failed, one of whom was colored.

**The British Columbia Medical Council** held its annual meeting, May 6, at Victoria, and elected the following officers: President, Dr. O. M. Jones, Victoria; vice-president, Dr. R. Eden Walker, New Westminster; registrar, Dr. Chas. J. Fagan, Victoria; and treasurer, Dr. W. J. McGuigan, Vancouver. On May 6 to 8 examination was given 11 applicants for license to practice.

**In Rhode Island**, the State Board of Health, at Providence, April 3, met 12 candidates, asked 70 written questions on 7 subjects and found only 1 unable to answer 75 per cent. correctly.

**Confederation of State Examining Boards.**—At Chicago, May 20, was held the second meeting of the American Confederation of Reciprocal Examining and Licensing Medical Boards. Representatives from the Wisconsin, Indiana, Illinois and Michigan boards were present and the details for the reciprocal exchange of certificates between Indiana, Wisconsin and Michigan were perfected upon the basis of the two qualifications passed at the January meeting of the Confederation, viz.: 1. That a license or certificate of qualification of at least one year's date and based on presentation of a satisfactory diploma, and an examination before a board in specified branches of medicine and surgery, may be accepted at the discretion of a board in lieu of an examination, and as a basis upon which the license of a state may be issued. 2. That a license or certificate of qualification issued by a state board of registration or medical examiners of at least one year's date, based upon presentation of a satisfactory diploma and on the recommendation of a state board of registration or medical examiners as to the reputability of the applicant, may be accepted at the discretion of a board in lieu of an examination, and as a basis upon which the license of a state may be issued. The boards of the above-mentioned states meet in June and will take such action then as will result in the immediate exchange of certificates. Prof. J. B. Murphy, of Northwestern University Medical School, and Prof. John N. Dodson, Dean of Rush Medical College, were present and spoke very strongly in favor of the objects of the confederation. The following officers were elected: President, Dr. J. R. Currens, Two Rivers, Wis.; vice-presidents, Drs. J. M. Dinnen, Fort Wayne, Ind., and W. F. Curryer, Indianapolis; secretary, B. D. Harrison, Sault Ste. Marie, Mich.; treasurer, W. A. Spurgeon, Muncie, Ind.; executive council, Drs. Harvey B. Dale, Oshkosh, Wis., William Bell, Belding, Mich., and J. C. Webster, Lafayette, Ind. The constitution is as follows:

**ARTICLE I.**—The name of this organization shall be the American Confederation of Reciprocal Examining and Licensing Medical Boards.

**ARTICLE II.**—The object of this confederation shall be to establish reciprocal relations between the medical examining and licensing boards of the states, territories, districts and provinces of the United States; the purpose of which being that thoroughly worthy and well-qualified physicians and surgeons who have been legally authorized to practice under the laws of one of said states, territories, districts or provinces, may be given legal authority and be admitted to practice in any state, territory, district or province represented in this confederation without a repetition of the tests of qualification to which said practitioner has submitted.

**ARTICLE III.**—The officers of this confederation shall be a president, first and second vice-presidents, secretary and treasurer, whose duties shall be those usual to said offices and who shall be elected annually by the confederation and retain their respective offices until their successors are elected and qualified.

**ARTICLE IV.**—Additional to the officers mentioned in Article III, there shall be an executive council, composed of an authorized representative of each state board represented in this confederation, whose duty shall be to take advisory oversight of the affairs of the confederation, audit claims and accounts and make recommendations as to the business affairs of the confederation.

**ARTICLE V.**—Any examining or licensing board of any state, territory, district or province of the United States having a medical practice law requiring an examination before said board and requiring thorough professional qualification as the basis of legal authority to practice in said state, territory, district or province, and providing for interstate reciprocity, shall be eligible to membership in this confederation and may obtain membership by the

signature of its authorized representative to this constitution and maintain such membership by compliance with the requirements of the constitution and by-laws of the confederation.

ARTICLE VI.—The annual dues to the confederation shall be such an amount proportioned among the boards composing the confederation as may be necessary to meet the expenses as found and allowed by the executive council.

ARTICLE VII.—It shall be the duty of each examining and licensing board having membership in this confederation to draft and spread on record in its home office, a resolution embodying the basis of reciprocal recognition of applicants from other reciprocating states.

## Married.

GEORGE W. BILLIG, M.D., Chicago, to Miss Glencora Bell of Streator, Ill., May 27.

BERNARD H. LUEHSMANN, M.D., to Miss Mary Schulte, both of Norway, Mich., May 11.

FRANK A. BROCKMEYER, M.D., to Miss Sadie A. Kelly, both of Canandaigua, N. Y., May 5.

ORA M. RHODES, M.D., Bloomington, Ill., to Miss Myrtle J. Downs, of Elwood, Ind., May 8.

ERNEST H. MADAJESKY, M.D., to Miss Ada Clark McMinn, both of Bessemer, Mich., May 7.

JOSEPH PETTYJOHN, M.D., acting-assistant surgeon, U. S. Army, to Miss Transon Senter, of Humboldt, Tenn., at Portland, Ore., May 1.

## Deaths and Obituaries.

Allen H. Hulshizer, M.D., born March 28, 1851, at Hughesville, N. J., died at his home in Philadelphia, May 19, from splenic leukemia. The deceased had been active in his profession in Philadelphia for a quarter of a century, and was unusually successful. His preliminary education was partially acquired at Lafayette College. For several years he was principal of the grammar school of Phillipsburg, N. J. In 1878 he was graduated from Jefferson Medical College, Philadelphia. For five years subsequently he was chief of clinic of the gynecological and obstetrical department at Jefferson. He was one of the original members of the Pennsylvania State Board of Medical Examiners, a position which he retained until January of this year. He was also a member of the medical department of the city civil service board. He had served the alumni association of his alma mater as its president for one term. He was prominent in business and religious circles as well. He was a visiting physician to St. Joseph's Hospital, a member of the medical club of the Medical Society, of the County Medical and State Medical Societies, and of the American Medical Association.

John Charles Earle, M.D. University of Maryland, Baltimore, 1845, a native of Queen Annes County, Maryland, and son of Hon. Richard Tilghman Earle, chief judge of the Second Judicial District of Maryland, died at his home near Easton, Md., May 17, aged 78. He was president of the Easton Board of Trade.

J. Newton Arnold, M.D. Albany (N. Y.) Medical College, 1862, surgeon for four years during the Civil war of the Seventh N. Y. Heavy Artillery, and a member of the American Medical Association, died at his home in Clyde, N. Y., May 17, from heart disease, aged 65.

William H. Andrews, M.D. New York University, 1882, a member of the Hampden Medical Society and of the American Medical Association, died at the House of Mercy Hospital, Springfield, Mass., May 19, from meningitis, after an illness of one week, aged 47.

Ervin L. Soule, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1900, was drowned while canoeing at Stroudwater, May 13. He served for a year on the house staff of Maine General Hospital and then located at South Portland.

Christopher P. Calhoun, M.D. Cincinnati College of Medicine and Surgery, 1873, died, May 18, from paralysis, at his home in Altoona, Pa., aged 60. He was a soldier in the Civil war and had served Bedford County in the state legislature.

Frank R. Reynolds, M.D. Rush Medical College, Chicago, 1884, a member of the American Medical Association, insane from ill health and financial troubles, committed suicide by hanging, in his barn in Eau Claire, Wis., May 22.

Charles S. Morse, M.D. Savannah (Ga.) Medical College, 1870, who had been Clerk of the Supreme Court of Texas for

twenty-one years, died at his home in Austin, May 13, after a prolonged illness, from Bright's disease, aged 53.

John A. Elliott, M.D. University of Buffalo (N. Y.), 1897, assistant physician at the Hudson River State Hospital, Poughkeepsie, N. Y., died suddenly from valvular heart disease at the hospital, May 12, aged 31.

John H. Morgan, M.D. University of Pennsylvania, Philadelphia, 1850, a practitioner of Clinton, Ind., died at a hospital in Terre Haute, Ind., May 11, shortly after an operation for anal fistula.

E. Boylston Jackson, M.D. Pennsylvania Medical College, Philadelphia, 1852, for 18 years a practitioner of Menomonie, Wis., died at the home of his daughter in St. Paul, Minn., May 14, aged 75.

Charles Y. Lord, M.D. Dartmouth Medical College, Hanover, N. H., 1877, died at the residence of his brother in Portland, Me., May 12, after an illness of several months, aged 47.

William T. Elder, M.D. Medical College of Ohio, Cincinnati, 1872, died, May 17, at his home in Nashville, Ohio, from the effects of an overdose of morphin, May 17, aged 60.

William R. Harris, M.D. Medical College of Georgia, Augusta, 1887, died at his home in Waterloo, S. C., May 12, from paralysis after an illness of only a few hours.

Walter M. Smith, M.D. Medical College of the State of South Carolina, Charleston, 1892, died, May 12, from neuralgia of the heart, at his home in Liberty, S. C.

Elizabeth P. Hay, M.D. Illinois Medical College, Chicago, 1895, died at Hot Springs, Ark., April 18, from diabetes, after an illness extending over several years.

James N. Clemmer, M.D. Cincinnati Medical College, 1853, a veteran of the Civil war, died at his home in Clarksville, Iowa, April 15, aged 75.

Edgar W. Moorehouse, M.D. Albany (N. Y.) Medical College, 1884, died suddenly at his residence in Peru, N. Y., May 13, from heart disease.

Reuben J. H. Tall, M.D. University of Maryland, Baltimore, 1865, died in Baltimore from consumption, May 12, after a long illness, aged 59.

Nathan E. Hooper, M.D. Kentucky School of Medicine, Louisville, 1884, died suddenly from apoplexy, at his home in Mexia, Texas, May 10.

Major John Brooke, M.D., a retired army surgeon, died suddenly of cerebral hemorrhage, at his home in Radnor, Pa., May 11, aged 72.

Cyrus Smith, M.D. Rush Medical College, Chicago, 1872, died at St. Barnabas' Hospital, Minneapolis, Minn., May 18, aged 70.

Stewart A. Fritts, M.D. Baltimore Medical College, 1893, died at his home in Wilmington, Del., May 16, from typhoid fever.

E. A. Goodsell, M.D., died at his home in Afton, N. Y., from pneumonia, May 13, after an illness of one week, aged 40.

J. H. Jenkins, M.D. University of Nashville, Tenn., 1886, died at his home in Oklahoma City, Okla., May 12, aged 55.

George W. McCoy, M.D. Louisville (Ky.) Medical College, 1883, died at his home in Chrisney, Ind., May 16, aged 48.

## Book Notices.

THE ACCESSORY SINUSES OF THE NOSE, Their Surgical Anatomy and the Diagnosis and Treatment of Their Inflammatory Affections. By A. Logan Turner, M.D. (Edin.), F.R.C.S. Ed., Surgeon for Diseases of the Ear and Throat, Deaconess Hospital, Edinburgh. With 40 Plates and 81 Figures. Cloth. Pp. 211. Price, \$4.00. New York: Longmans, Green & Co. 1902.

This volume is based on a lecture on the air sinuses of the skull delivered before the Royal College of Surgeons of Edinburgh, and a prize essay on "The Racial Characteristics of the Frontal Sinuses, Based Upon an Examination of 578 Skulls," which received the surgical prize of the Royal College of Surgeons in 1899. The author has added additional observations on the surgical anatomy of the maxillary sinus, the ethmoidal cells, the sphenoidal sinus, etc., also with two chapters on diagnosis and a treatment of the inflammatory affections of the nasal accessory sinuses. We do not notice, however, any mention of the absence of the naso-antral septum which, as Talbot has shown, may be wanting and the antrum simply a cavity directly connected with the nasal passage, or may be

simply a minute cavity situated well to one side, the rest of the hollow of the bone being really a part of the nose. In fact, the variations of these facial sinuses are almost innumerable, and while the author does exceedingly well in pointing out some of the variations of the frontal sinus which have been apparently neglected by other writers, his work is not complete as regards some of the less important but still notable peculiarities that may exist in the antrum.

**DISINFECTION AND DISINFECTANTS.** A Treatise upon the Best Known Disinfectants, Their Use in the Destruction of Disease Germs, with Special Instruction for Their Application in the Commonly Recognized Infectious and Contagious Diseases. By H. M. Bracken, M.D., Professor of Materia Medica and Therapeutics, University of Minnesota. Second Edition. Cloth. Pp. 129. Price, \$1.00. Chicago: Trade Periodical Company. 1901.

Dr. Bracken has within a year found it necessary to bring out a second edition of his very convenient little manual, which fact speaks well for its merits and their appreciation by those who are interested in its subject. It may be taken as an up-to-date exposition of the leading facts of its subject, prepared by a master in the specialty of sanitation. Its author is a little extreme in his precautions in some respects, we hardly think that many sanitary officials—not even smallpox inspectors—utilize the Kuklux suit he says physicians attending infectious diseases should wear, nor do we believe that disinfectors generally adopt the light-of-the-harem costume here illustrated. The recommendations, however, are on the safe side, and we can say that the book is one that ought to go through many more rapidly appearing editions. It is about the handiest and certainly one of the most reliable little manuals of its kind.

**GENITO-URINARY DISEASES AND SYPHILIS.** For Students and Practitioners. By Henry H. Morton, M.D., Clinical Professor of Genito-Urinary Diseases in the Long Island College Hospital. Illustrated with Half-tones and Full-page Color Plates. Pp. xii-372. Price, extra cloth, \$3.00 net. Philadelphia: F. A. Davis Company, Publishers.

This volume of nearly 400 pages, while less elaborate and complete than some on the subject, seems to be reasonably full and to give on the whole a good idea of its subject. It is amply illustrated, and while there are some points in which the author may differ from others it is a good book for the practitioner. For him, in fact, it is intended rather than for the specialist. We do not see any mention, however, of one or two things that are not quite so recent, but that they might have been noticed, such as, for example, the Harris segregator, the relief of kidney tension by nephrotomy and one or two other matters. The author speaks well of one or two methods which we had supposed had rather gone out of favor with most specialists, such as castration and vasectomy for prostatic hypertrophy. He seems to see a large field of usefulness for these operations. On the whole, the book is one that we should say ought to meet with favor by the profession.

**STUDIES IN THE PSYCHOLOGY OF SEX. SEXUAL INVERSION.** By Havelock Ellis, L.S.A. (England): Fellow of the Medicolegal Society of New York and the Anthropological Society of Berlin. Pp. xi-272. Size, 8 $\frac{1}{2}$  x 5 $\frac{3}{4}$  inches. Extra Cloth, \$2.00 net. Philadelphia: F. A. Davis Co. 1901.

The appearance of a second edition of a work within a year or two of its first appearance is usually a sign of its merits, and commands, in a sense, a favorable opinion. In the case of this book this can hardly be asserted—it ought never to have had a second edition. As originally published it had its value—it was a research into a subject of some interest to special students in certain lines, and in their libraries and in the limited reference list of general libraries it had its place. The appearance of this second edition indicates a morbid demand that ought not to have been complied with; the work, out of print, yet still available to those who ought to read it in public libraries, would have been all that science required. We presume, however, that it is profitable to its publishers and it may repeat the record of the ten or a dozen editions of Krafft-Ebing's work, unless Anthony Comstock interferes.

**TEXT-BOOK OF ANATOMY AND PHYSIOLOGY FOR NURSES.** Compiled by Diana Clifford Kimber, Graduate of Bellevue Training School. Cloth. Pp. 275. Price, \$2.50. New York: The Macmillan Co. 1902.

This is the second edition of a book that has already been before the medical public for some years. The author states that it has been extensively revised, and from the assistance

she has had we should think that it is thoroughly up to date. What the nurse ought to know in regard to physiology and anatomy seems to be pretty well comprised within these pages. A valuable feature of this book is an extensive glossary at the end. While a large part of the book is given up to the subject of physiology, we notice that the pages are all headed "Anatomy for Nurses," which strikes one as an oversight, though of slight importance. The illustrations appear to be generally very good and are sufficiently numerous to be a valuable aid to the class of readers for which it is intended.

**LESSONS ON MASSAGE.** By Margaret D. Palmer, Masseuse and Manager of the Massage Department of the London Hospital. Cloth. Pp. 234. Price, \$2.00. New York: Wm. Wood & Co. 1901.

This little work appears to be a convenient and fairly good description of massage manipulations and also contains a general treatment of the anatomy, a knowledge of which will be of use to the masseur or masseuse. In fact, a large portion of the book is taken up with this and the part on massage is comparatively brief. The average manipulator will, however, probably find in it all that is absolutely necessary, though there are special matters which are scarcely mentioned. The instructions given are founded upon the results of many years' experience both in teaching and practical work, which fact should be in itself to some extent a guarantee of its value.

**QUAIN'S DICTIONARY OF MEDICINE.** By Various Writers. Third Edition. Largely Rewritten and Revised Throughout. Edited by H. Montague Murray, M.D., F.R.C.P., Joint Lecturer on Medicine, Charing Cross Medical School. Assisted by John Harold, M.B., B.Ch., B.A.O., Physician to St. John's and St. Elizabeth's Hospital, and W. Cecil Bosanquet, M.A., M.D., M.R.C.P., Physician to Out-Patients, Victoria Hospital for Children, Half Morocco. Pp. 1892. Price, \$10.00. New York: D. Appleton & Co. 1902.

The third edition of this standard English encyclopedia on the practice of medicine and allied subjects has been thoroughly revised and new space given to the special branches. The colored plates and cross references between related subjects add to its value. The second edition was in two volumes, and this is in one, and we consider the change not an improvement. Those for whom a foreign work will suffice will find this a valuable book of reference.

**A LABORATORY COURSE IN BACTERIOLOGY.** For the Use of Medical, Agricultural, and Industrial Students. By Frederick P. Gorham, A.M., Professor of Biology, Brown University. With 97 Illustrations. 12mo. Volume. Cloth. Pp. 198. Price, \$1.25 net. Philadelphia and London: W. B. Saunders & Co. 1901.

The study of bacteriology is calling out a numerous list of text-books, and the present volume appears to be one that will meet a demand for an introduction to the subject. It necessarily has its deficiencies, but, within its compass gives apparently a fair exposé of the common laboratory methods. The lack of colored illustrations may seem to some a defect, but on the whole it is well illustrated, and in other respects the make-up is very fine. The book is of a handy size, and this is a decided advantage in the wide range of instruction for which it is designed.

**THE CAUSES OF DEATH AMONG THE ASSURED IN THE SCOTTISH WIDOWS' FUND AND LIFE ASSURANCE SOCIETY.** From 1874 to 1894 inclusive. Reported by Claud Muirhead, M.D., F.R.C.P.E., Medical Officer of the Society. Cloth. Pp. 81. Edinburgh: R. & R. Clark, Ltd. 1902.

This work embraces the results of a careful study of the mortality of a large assurance society for a period of twenty-one years, and includes a consideration of 9163 deaths. It is worthy of note that in this list no death from appendicitis appears. Considerable space is devoted to the discussion of deaths from consumption and cancer. The death rate from the former is found to be steadily diminishing, while the cancer death rate is as steadily increasing. The work will be found of value to all interested in life insurance problems.

**"FIRST AID" to the Injured and Sick.** An Ambulance Handbook. By F. J. Warwick, B.A., M.B., Cantab., M.R.C.S., L.S.A., Associate of King's College, London, and A. C. Tunstall, M.D., F.R.C.S., Ed., Surgeon-Captain Commanding the East London Volunteer Brigade Bearer Company. Cloth. Pp. 232. Price, \$1.00. Philadelphia and London: W. B. Saunders & Co. 1901.

This ambulance handbook possesses certain advantages over the ordinary first aid text-book in that it is neither too diffuse nor too concise. It follows the accepted rule, and contains a great deal of valuable information well and tersely expressed. It will prove especially useful to the volunteer first aid and hospital corps men of the National Guard.

## Association News.

### Rate of One Fare Plus Two Dollars Granted for Saratoga Round Trip.

As editorially noted in this issue, the Committee on Transportation has secured a further reduced rate to the Saratoga meeting. The Trunk Line Association, and with it the roads east of Chicago, have agreed to the rate of one fare and \$2 for the round trip. This will without doubt be agreed to by the Western Association, unless the time be too short for the arrangement. This new rate will do away with certificates. A round trip ticket will be sold from any point east of Chicago and, it is hoped, from any point west, for one fare plus \$2. The time limits of these tickets will be the same as previously announced. Tickets will be on sale June 4 to 13, and will be good on a return trip starting not later than June 17. Those who wish to return later than June 17 may deposit their tickets with the Saratoga ticket agent previous to June 17, and, on payment of a fee of fifty cents, have the time extended so as to begin the return trip on or before July 2.

### Representatives from State Societies to the House of Delegates of the American Medical Association.

The following have been officially certified to the Secretary as representatives:

Alabama—W. H. Sanders, Mobile; W. M. Wilkerson, Montgomery.  
 Arizona—  
 Arkansas—J. A. Dibrell, Little Rock.  
 California—H. Bert Ellis, Los Angeles.  
 Colorado—C. K. Fleming, Denver.  
 Connecticut—  
 Delaware—Willard Springer, Wilmington.  
 District of Columbia—George M. Kober, Washington.  
 Florida—R. D. Murray, Key West.  
 Georgia—James B. Morgan, Augusta; Floyd W. McRae, Atlanta.  
 Idaho—Ed. E. Maxey, Boise.  
 Illinois—  
 Indian Territory—  
 Indiana—G. W. H. Kemper, Muncie; Edwin Walker, Evansville; William N. Wishard, Indianapolis; D. C. Peyton, Jeffersonville.  
 Iowa—  
 Kansas—J. E. Minney, Topeka.  
 Kentucky—J. N. McCormack, Bowling Green; Thomas Hunt Stucky, Louisville.  
 Louisiana—  
 Maine—Seth C. Gordon, Portland.  
 Maryland—William H. Welch, Baltimore; William Osler, Baltimore.  
 Massachusetts—W. T. Councilman, Boston; H. E. Marion, Brighton; J. Collins Warren, Boston; F. C. Shattuck, Boston; C. H. Williams, Boston; J. F. A. Adams, Pittsfield.  
 Michigan—H. O. Walker, Detroit; V. C. Vaughan, Ann Arbor.  
 Minnesota—A. W. Abbott, Minneapolis.  
 Mississippi—J. C. Hall, Anguilla.  
 Missouri—  
 Montana—  
 Nebraska—H. M. McClanahan, Omaha.  
 New Hampshire—Ira J. Prouty, Keene.  
 New Jersey—E. J. Marsh, Paterson; Chas. J. Kipp, Newark; Luther M. Halsey, Williamstown.  
 New Mexico—G. C. Bryan, Alamogordo.  
 New York—E. E. Harris, New York; C. A. Wall, Buffalo; H. O. Arrowsmith, Brooklyn; E. D. Ferguson, Troy; Chas. E. Quimby, New York.  
 Nevada—  
 North Carolina—James A. Burroughs, Asheville; H. A. Royster, Raleigh.  
 North Dakota—I. N. Wear, Fargo.  
 Ohio—  
 Oklahoma—  
 Oregon—Andrew C. Smith, Portland.  
 Pennsylvania—William S. Foster, Pittsburg; George W. Guthrie, Wilkesbarre; A. P. Hull, Montgomery; W. T. Bishop, Harrisburg; H. S. McConnell, New Brighton; John B. Roberts, Philadelphia; William M. Welch, Philadelphia; Webster B. Lowman, Johnstown.  
 Rhode Island—John Champlin, Westerly.

South Carolina—  
 South Dakota—  
 Tennessee—W. Frank Glenn, Nashville.  
 Texas—H. A. West, Galveston.  
 Utah—  
 Vermont—D. C. Hawley, Burlington.  
 Virginia—  
 Washington—Park Weed Willis, Seattle.  
 West Virginia—  
 Wisconsin—W. T. Sarles, Sparta; J. R. Barnett, Neenah.  
 Wyoming—R. Harvey Reed, Rock Springs.  
 United States Marine-Hospital Service—Walter Wyman, Washington, D. C.  
 Medical Department U. S. Army—D. M. Appel, Ft. Bayard, N. M.  
 Medical Department U. S. Navy—R. A. Marmion, Washington, D. C.

### Delegates from the Sections.

Practice of Medicine—J. M. Anders, Philadelphia; Norman Bridge, Los Angeles.  
 Surgery and Anatomy—C. A. Powers, Denver; A. D. Bevan, Chicago.  
 Obstetrics and Diseases of Women—L. S. McMurtry, Louisville; W. H. Humiston, Cleveland, Ohio.  
 Hygiene and Sanitary Science—  
 Ophthalmology—J. A. Lippincott, Pittsburg, Pa.; H. V. Würdemann, Milwaukee.  
 Diseases of Children—S. W. Kelly, Cleveland, Ohio; A. C. Cotton, Chicago.  
 Stomatology—G. V. I. Brown, Milwaukee; A. E. Baldwin, Chicago.  
 Nervous and Mental Diseases—H. A. Tomlinson, St. Peter, Minn.; H. N. Moyer, Chicago.  
 Cutaneous Medicine and Surgery—W. L. Baum, Chicago; W. T. Corlett, Cleveland, Ohio.  
 Laryngology and Otology—Emil Mayer, New York City; Geo. C. Stout, Philadelphia.  
 Materia Medica, Pharmacy and Therapeutics—O. T. Osborne, New Haven, Conn.; A. B. Lyons, Detroit, Mich.  
 Physiology and Pathology—W. A. Evans, Chicago; Alfred Stengel, Philadelphia.

**Maryland Public Health Association.**—This Association will hold its annual meeting, June 3 and 4, at Denton, and every local board of health has been invited to attend.

**Hudson County (N. J.) Medical Association.**—Dr. Oliver R. Blanchard, Jersey City, was elected president of this Association at the annual meeting held in Jersey City, May 7.

**Tazewell County (Ill.) Medical Society.**—A number of physicians of Tazewell County met at Tremont, April 20, and organized this Society, with Dr. William H. Conibear, Morton, as president, and Dr. Carl G. Muehlmann, Pekin, secretary and treasurer.

**Winnebago County (Iowa) Medical Society.**—The annual meeting of this Society was held at Forest City, May 15. Dr. Charles E. Keeler, Lake Mills, was elected president; Dr. Peter H. Vesterborg, Forest City, vice-president; Dr. Luther Wall, Leland, secretary, and Dr. Gissle M. Lee, Thompson, treasurer.

**Gallia County (Ohio) Medical Society.**—At the annual meeting of this Society in Gallipolis, May 6, the following officers were elected: Dr. Jehu Eakins, Patriot, president; Drs. Theodore L. Chadbourne, and S. W. Williams, Gallipolis, vice-presidents; Dr. John B. Alcorn, Gallipolis, secretary, and Dr. W. E. Howell, Rio Grande, treasurer.

**Genesee County (N. Y.) Medical Association.**—At the annual meeting of this Association held in Batavia, May 14, memorial resolutions were adopted regarding the late president of the Association, Dr. Morris W. Townsend, Bergen. Dr. Frank L. Stone, Le Roy, was elected president; Dr. Emerson E. Snow, Batavia, vice-president, and Dr. Annie M. Cheney, Batavia, secretary and treasurer.

**Erie County (N. Y.) Medical Association.**—A largely attended meeting of the Erie County Medical Association was held at the University Club of Buffalo, May 15. Dr. John Parmenter read a paper on "Colles Fracture," which was discussed by Drs. William Phelps and Eugene Smith. Dr. Julius Ullman read a paper on "Brewers' Yeast in Therapeutics," which was discussed by Drs. De Lancey Rochester and Allen A. Jones.

**San Francisco County (Cal.) Medical Society.**—At the regular monthly meeting, May 13, Dr. Sanford Blum read a paper on "Endocarditis in Infancy and Childhood." Dr. William F. Cheney read a paper entitled "Lobar Pneumonia in Infancy," giving an extensive narration of the diagnosis. The Society unanimously adopted a resolution providing for affiliation with the State society under its new constitution, in conformity with the plans of the American Medical Association.

**Marion County (Iowa) Medical Society.**—At the annual meeting of this Society, held May 8, in Knoxville, the following officers were elected: Dr. Benjamin F. Keables, Pella, president; Drs. John V. Brann, Knoxville, Clarence E. James, Durham, and Miles J. Duncan, Pleasantville, vice-presidents; Dr. Corwin W. Cornell, Knoxville, secretary; Dr. Allen J. Nossaman, Pella, assistant secretary, and Dr. John V. Brann, Knoxville, treasurer. At the banquet in the evening Judge Crozier delivered an address on "Expert Testimony."

**Kansas Medical Society.**—Under the presidency of Dr. Lewis H. Munn, Topeka, this Society met at Lawrence for its thirty-sixth annual convention, May 7. Judge S. A. Riggs welcomed the Society to Lawrence, and Dr. James W. Ryan, Coffeyville, responded. The members were entertained at a banquet and smoker, and also witnessed experiments with liquid air. The following officers were elected: Dr. James W. May, Kansas City, president; Drs. John H. Brierley, Glasco, and Charles S. Hullman, Columbus, vice-presidents; Dr. William E. McVey, Topeka, recording secretary; Dr. Henry O'Donnell, Ellsworth, corresponding secretary; Dr. Lewis H. Munn, Topeka, treasurer, and Dr. Samuel G. Stewart, Topeka, librarian. The 1903 meeting will be held in Concordia.

**Nebraska State Medical Society.**—The thirty-fourth annual meeting of this Society was held in Omaha, May 6, 7 and 8, under the presidency of Dr. William B. Jely, University Place. Rev. Frederick A. Hatch welcomed the visitors to Omaha, and Dr. James L. Greene, Asylum, responded on behalf of the Society. The president's address was on "The Unity of Scientific Medicine." Elaborate entertainments were given the visiting members and ladies. The next meeting is to be held in Lincoln. The officers for the ensuing year are: Dr. Allen B. Anderson, Pawnee City, president; Drs. Andrew D. Nesbit, Tekamah, and Byron B. Davis, Omaha, vice-presidents; Dr. A. D. Wilkinson, Lincoln, recording secretary; Dr. H. Winnett Orr, Lincoln, corresponding secretary and librarian, and Dr. James L. Greene, Asylum, treasurer.

**Arkansas Medical Society.**—At the twenty-seventh annual meeting, held in Little Rock, May 13, 14 and 15, the Society was reorganized on the lines recommended in THE JOURNAL of May 3, and the constitution adopted with only a few unimportant modifications. The meeting was well attended and enthusiastic. In addition to the regular program a reception

was given by Dr. and Mrs. Edwin and Carle E. Bentley; a tally-ho drive was arranged for the ladies; the retiring president, Dr. Frank Vinzonhaler, gave a reception at his residence, and the annual banquet was given, May 14, under the auspices of the Little Rock Medical Society. The following officers were elected: Dr. Charles R. Shineault, Helena, president; Drs. William N. Yates, Fayetteville, Leonidas Kirby, Harrison, and William A. Brown, Monticello, vice-presidents, and Drs. Joseph P. Runyan, Little Rock, and Richard C. Thompson, Pine Bluff, were re-elected secretary and treasurer, respectively. The next meeting will be held in Jonesboro, May 12-14, 1903.

**Buffalo Academy of Medicine.**—Prof. Simon Flexner of the University of Pennsylvania addressed the Section on Pathology, May 20, on "Dysentery and Its Causes." Dr. Charles G. Stockton presiding. He stated that since the discovery of the bacillus of dysentery (Shiga) that the pathology of this disease had become much simplified, and that the two causes of dysentery may be divided into a bacillary and amebic form, the bacillary being the form associated with pseudo-membranous formation, the amebic with ulcerations. During the summer of 1900, with a commissioner sent out from Johns Hopkins Hospital, the privilege was granted him and his associates of studying the dysentery of the Philippines, and Shiga's bacillus, which gives the agglutination test with serum of the affected case, could be isolated in all cases of dysentery in United States soldiers. The same was done in some institutional cases in abundance at New Haven, Conn., and at Lancaster, Pa., and in soldiers returning with the disease from the Philippines demonstrating that the cases of dysentery occurring in this country are due to the Shiga bacillus. Professor Flexner stated that great hopes are entertained by him for a serum and for vaccination against the disease. He has already done considerable work in this direction and believes great good can be accomplished. During the coming summer he will experiment on these lines.

**The American Therapeutic Society.**—The third annual meeting of this Society was held in the New York Academy of Medicine, May 13, 14 and 15, under the presidency of Dr. Reynold W. Wilcox, New York City. A notable feature of the first day's meeting was a symposium on "Valvular Diseases of the Heart." Dr. Thomas E. Satterthwaite, New York City, took up the etiology and symptomatology; Drs. Thomas L. Coley and Albert C. Barnes, Philadelphia, and Dr. William H. Porter of New York City discussed the treatment; Dr. Leonard Weber, New York City, spoke on the prognosis, and Dr. Oliver T. Osborne, New Haven, Conn., took part in the general discussion. The special feature of the second day was a symposium on "The Treatment of Pulmonary Tuberculosis." Dr. George E. Tyler, Denver, Colo., discussed the climatic treatment; Dr. Jesse Shoup, Washington, D. C., the medical treatment; Drs. William H. Porter, New York City, and Olin Leech, Washington, D. C., the dietetic treatment, and Dr. Egbert LeFevre, New York City, the physical treatment. The afternoon session was entirely devoted to a complete series of papers, representing the various specialties, and reporting advances in special therapeutics. The third day was marked by the presentation of an excellent résumé of "The Therapeutic Use of the Organic Extracts," by Dr. Oliver T. Osborne, New Haven, Conn. Dr. De Forest Willard, Philadelphia, also contributed a very practical paper on "The Treatment of Gonorrheal Arthritis." The following officers were elected: Dr. Thomas E. Satterthwaite, New York City, president; Drs. Howard H. Baker, Washington, D. C.; Josiah N. Hall, Denver, and Oliver T. Osborne of New Haven, Conn., vice-presidents, and Dr. Noble P. Barnes, Washington, D. C., secretary.

#### PHILADELPHIA OBSTETRICAL SOCIETY.

*Monthly Meeting, held May 1.*

President, Dr. John M. Fisher, in the Chair.

#### The Etiology and Diagnosis of Fractures in the Newborn.

Dr. W. REYNOLDS WILSON, in this paper, said that the common fractures occur in the following order as to frequency: 1, the humerus; 2, the clavicle; 3, the femur; 4, the cranium. Traumatic fracture is usually due to obstetric manipulation. In diagnosis, the possibility of epiphyseal separation, congenital luxation, epiphyseal osteitis of syphilitic origin and obstetric paralysis may increase the difficulty in diagnosis. The infant's cry, indicative of pain, and the disability to motion, swelling, undue mobility, are evidences of fracture. The dif-

ferentiation between fracture and dislocation is sometimes obscured by the presence of fat in overgrown children.

DR. EDWARD P. DAVIS stated that the fractures of the long bones which he had seen had, as a rule, recovered without deformity, the treatment being some simple splint dressing, with a bandage.

DR. L. J. HAMMOND thought that he had seen obstetric fracture from contraction of the vaginal sphincter. Fractures of the newborn, he stated, are often difficult to diagnose, the diagnosis frequently resting only upon the presence of swelling, tenderness and evidence of pain on motion.

DR. WILSON, the author of the paper, pointed out that in extraction of a fetus in breech presentation, the risk of fracturing an extended arm, in bringing it down, is great. He cited a case in which he had difficulty in delivering one of the thighs after version, and in which he believes he avoided a fracture of the thigh by waiting for more complete dilatation of the cervix.

#### Polyhydramnios.

DR. EDWARD P. DAVIS read an excellent paper entitled "Polyhydramnios; Its Differential Diagnosis and Treatment, with the Report of Cases." By polyhydramnios is meant more than two pints of amniotic liquid at full term. The pathology is not fully known. Many conditions accompany polyhydramnios. The placenta is often large, dropsical and infiltrated, Jungbluth's vessels often enlarged, amnion and chorion may be thickened with extensive fissures in the epithelial layer of the amnion and fatty degeneration of cells. By experiment, seven times more fluid passes through veins than through arteries of cord into the placenta. Any fetal condition causing venous engorgement tends to produce polyhydramnios, as may also irritating substances formed in lymphatics. It does not result from increased renal action in the fetal kidneys. Excessive secretion from the cerebrospinal canal of the fetus may contribute. Polyhydramnios is normal at the fourth month and its persistence results from failure in normal development. By cryoscopy further information regarding the osmotic properties of maternal and fetal blood and of the liquor amnii may increase our knowledge. Bacteriology gives no information.

The diagnosis is made by first diagnosing pregnancy, then by observing that in polyhydramnios we can usually obtain evidence of faint uterine contraction and can often insert the finger through the cervix and detect a presenting part. Ectopic gestation must be kept in mind as polyhydramnios may complicate ectopic pregnancy. In ovarian cyst the illness is longer, the swelling at first unilateral. The intermittent hardening of the tumor is absent and the uterus can be found but little enlarged. In ascites the dulness changes when the position of the patient is altered.

When pregnancy is found, a second diagnosis must be made to recognize or eliminate the presence of pregnancy and ovarian cyst, pregnancy and ascites, plural pregnancy, an hydatid mole, a very large child or a malformed fetus. In hydatid mole, the pear-shaped uterus has little fluctuation and there is repeated discharge of blood. In large or malformed fetus the heart can usually be heard and palpation reveals the child. While twin pregnancy can generally be recognized it may be completely mistaken for polyhydramnios. In exceptional cases, ovarian cyst complicating pregnancy may be difficult to diagnose and exploratory incision may be necessary.

Attention is called to misleading phenomena, the absence of such tension upon the membranes as would be expected from the quantity of amniotic liquid and also the absence of early shortening of the cervix.

Treatment by drugs is without value. When polyhydramnios is slight and not increasing, the patient's health remaining good, pregnancy should not be interrupted. When distention increases rapidly and the patient's health is impaired, under thorough antiseptic precautions the cervix should be dilated sufficient to admit the finger. A pair of uterine dressing forceps, closed, should be inserted and the membranes ruptured, the forceps opened and a rent sufficiently large made to permit the introduction of the finger. Fluid should be allowed to escape very gradually until the presenting part descends firmly against the cervix. Firm pressure must be made

over the abdomen by a many-tailed abdominal binder or broad bandage held by assistants. The patient must be watched as labor is often precipitate and the fetus may assume unfavorable positions. Labor should not be hurried in the interests of the child because the fetus is often deformed.

Polyhydramnios is dangerous to the mother from over-distention, relaxation, hemorrhage and increased danger of sepsis. The uterus must be completely emptied and made to contract. A hot intra-uterine douche of 1 per cent. lysol, tamponing with iodoform gauze, the hypodermic use of strychnia and ergot and other stimulation are necessary.

Occasionally, after abdominal section, the excess of amniotic liquid has disappeared by absorption.

#### Discussion.

DR. E. E. MONTGOMERY said that it is frequently difficult to differentiate this condition from abdominal tumors, especially ovarian cysts. Polyhydramnios affords a tendency to septic infection because of the enormous distention of the uterine walls, causing an anemia of the organ with engorgement of its vessels.

DR. JOHN C. DACOSTA cited a case in which, after the cervix was partly dilated, he had punctured the membranes some distance above the internal os, so that the amniotic fluid escaped slowly.

DAS. STRICKER COLES and LONGAKER reported cases.

DR. DAVIS closed the discussion. He regarded the absence of uterine thinning as due to a hyperplasia of the wall, and the absence of tension of the membranes and of obliteration of the cervix as due to such a degree of uterine distention as to prevent efficient contractions.

#### Transverse Position with Impaction.

DR. STRICKER COLES next reported six cases of transverse position of the child with prolapse of the arm and impaction. He said that this condition was nearly always due to a neglect of a transverse position, as such cases would rarely terminate by spontaneous version or evolution. When the child's back is posterior the back becomes wedged under the promontory of the sacrum, and to do version, the child had to be pushed entirely out of the pelvis, which was dangerous, as the uterus was in tetanic contraction and would probably be ruptured. When the back was anterior it could be shoved up in a rotary movement, sweeping along the anterior wall of the uterus, causing very little movement of the head and breech. The formation of the wedge, he said, was due to elongation of the child's neck making the head and breech on the same level with the upper arm, the three forming the base of the wedge and the prolapsed arm the point of the wedge. The dangers are rupture of the uterus and sepsis, the latter being often due to pressure necrosis and to the entrance of bacteria before delivery, the labor usually lasting from one to three days.

The treatment the speaker employed was version, under deep chloroform anesthesia, first emptying the bladder and rectum, washing the external genitalia and adjacent parts with soap and water, sterile water, and bichlorid solution, and douching the vagina with 2 per cent. lysol. In cases where the back was posterior, the arm prolapsed and gangrenous, decapitation should be done at once, with long, blunt-pointed scissors or Braun's hook; no attempt at version should be made. After decapitation, traction on the arm would easily deliver the body and the head could then be delivered with forceps. If decapitation is impossible, amputate the prolapsed arm and then bring down the other arm, which may be amputated. This would break up the wedge, and by moving the head slightly upward and inward, the operator can easily bring down the anterior or both feet.

In the first position, back anterior, it is often easy to push the back up and bring down a foot. After delivery, remove the placenta and membranes, douche the uterus with 1 per cent. lysol solution, and pack the uterus with iodoform gauze. This will lessen the danger of hemorrhage, drain the uterus well, and will diminish the danger of sepsis; the gauze is to be removed in thirty-six hours, and the uterus irrigated with 1 per cent. solution of lysol.

If following this there should be rise of temperature and foul lochia, great care should be exercised in euretting and irrigating the uterus, as there will often be found a slough of the uterine wall which extends to the peritoneum, and there will be only the latter separating the uterine and abdominal cavities: the peritoneum, in such a case, would be easily punctured.

#### Report of Cases.

DR. CHARLES S. BAENES followed with a "Report of Two Cases of Transverse Position of the Fetus with Prolapse of an Arm and Inaction." Both cases had been neglected; the writer was not summoned until the condition existed; and the fetuses were dead. In the first case, the mother was of good muscular and nervous development and was not exhausted; in the second, opposite conditions existed. Both pelvis were contracted, and in the latter case there was much relaxation of the uterine and abdominal muscles. Pelvic contraction and muscular relaxation are the causes assigned for the malposition. In both cases delivery was accomplished under chloroform anesthesia, by internal podalic version; in the first, preceded by shoulder amputation of the prolapsed arm. The emptied uterus was douches with 1 per cent. lysol solution and packed with iodoform gauze as a precaution against infection and uterine relaxation and hemorrhage. The first case promptly recovered. The second died within a few hours, of exhaustion from prolonged labor with shock necessarily attending anesthesia and delivery. Necropsy failed to show any lesion; there was general anemia, flabbiness and friability of tissue, indicating little power of resistance.

If the cases had been seen early in labor, the writer believes that the chance of saving both children would have been good, and that the life of the mother lost, would not, in all probability, have been sacrificed. The presence of a midwife was responsible for the death of the mother, in that the summoning of proper aid was thereby deferred too long. Loss of the mother is presented as a warning against major obstetric operations in exhaustion, except they be done with plenty of assistants, fair surroundings, and all the essentials at hand for successful combat against shock.

A few statistics were cited showing that in nearly 23,000 cases of obstetrics 3 per cent. were of transverse position. What is believed to be two of the most common causes of the malposition, pelvic contraction and relaxation of uterine and abdominal walls, were illustrated in these cases.

The author stated that a physician owes it to himself, to his profession, and especially to his obstetric patient, to make it a routine practice to know her pelvic measurements and the position and presentation of the fetus in the latter months of pregnancy. It is only by such painstaking care that the fatal complications of obstetrics, such as result in neglected cases of transverse position, may be minimized. If the condition be diagnosed early and intelligent assistance (some form of version) be rendered, the prognosis for the child is fair, and for the mother good.

#### Discussion on Transverse Position.

DR. RICHARD C. NORRIS expressed regret that the two speakers in presenting the last subject had not discussed the contraindications for version. He considers Bandl's ring, when present, a contraindication. In such a case he would do embryotomy. For version, he thinks the Trendelenburg position a safeguard against uterine rupture. Amputation of the arm he considers sometimes an advantage, but cautioned against the danger of amputating the arm of a living fetus. While formerly an ardent advocate of intruterine douching, he now does not employ it and believes it to be of no especial value.

DR. DAVIS stated that he has recourse to Bandl's ring and distention of the lower uterine segment as a danger signal. In such a condition decomposition of the fetal wedge should not be attempted without some form of embryotomy. Chloroform he considers best for version because of its relaxing effect upon the uterine muscles. In regard to intrauterine douching, he does not regard it necessary except in cases where there is pressure necrosis, there has been entrance of air, or there is a tendency to uterine relaxation. Such douching should be fol-

lowed by packing with iodoform gauze to prevent relaxation and hemorrhage, to promote drainage and to serve as an antiseptic application. The speaker knows of no condition more serious than a case of a dead fetus in a contracted pelvis. He recently lost a mother of shock, the child having been delivered by embryotomy.

DR. NICHOLSON asserted his belief that in too many cases the loss of life was due to neglect or ignorance of those in the profession, and that such an opprobrium should not exist.

DRS. COLES and BARNES closed the discussion.

#### TEXAS MEDICAL ASSOCIATION.

*Thirty-fourth Annual Meeting, held at Dallas,*

*May 6 to 8, 1902.*

#### Statistical Report.

There was a good attendance and the secretary's report showed a membership of 373, to which 175 additions were made during the meeting. The report of the board of examiners stated that the work of registration is proceeding satisfactorily, over one thousand practitioners having enrolled themselves last year, the first year of the board's existence. The treasurer's report showed a balance of about \$2000 in the treasury.

#### Address of Welcome.

An address of welcome was delivered by the Mayor of Dallas, and at a later stage of the proceedings the Governor of the state was introduced and, speaking in the double capacity of a state official and the son of a physician, promised the association all the support in his power in their efforts to put the profession in the state on a higher and more satisfactory plane.

#### Plan of Reorganization.

The principal business in executive session was the consideration of a revision of the constitution and by-laws with the view of bringing them into harmony with the American Medical Association. The committee presented a majority and a minority report, the point of difference between them being as to whether the members of affiliated societies should be required to be members also of the state association. Both reports were referred to a large representative committee and, after hearing its report, the association decided to leave the whole matter over for another year in order to get a full expression of opinion from the profession. The minority report advocated the plan suggested by the American Medical Association, namely, that all members of affiliated societies should also be required to belong to the state association.

#### The Treatment of Tuberculosis.

This was the subject of an address by the chairman of the section on general medicine, Dr. J. W. Scott, Houston. As a result of recent progress in the knowledge of the etiology, diagnosis and treatment, physicians approach a case of consumption now with far more hopefulness as to the ultimate outcome than ever before in the history of medicine. Until recently they had treated this disease in a very perfunctory manner, but at the present time the up-to-date physician attacks it with a zeal and earnestness worthy of the foe he is combating. The state of Texas has always made persistent and determined efforts to protect its citizens from yellow fever, but has completely ignored this greater, deadlier and infinitely more common infection of tuberculosis.

#### The Poisonous Snakes and Spiders of Texas.

Dr. H. W. Crouse, Victoria, in a contribution under this title, presented the results of a long series of experiments, his main object being to furnish the general practitioner with ready means of distinguishing the bites of different kinds of snakes and spiders and of thus being in a position to apply the requisite remedies. The general treatment found most efficacious consisted of permanganate of potassium injected locally and also administered by the mouth, strychnin, small doses of alcohol and rest. The popular idea that alcohol was an antidote was a mistake. Though useful in conjunction with the other remedies mentioned, it seemed when given alone to rather add to the virulence of the poison.

### Pneumonia.

A symposium on this subject was given by Drs. R. W. Knox, S. C. Red and R. T. Morris, Houston, the discussion on which showed marked difference of opinion on the value of creosote and the so-called specifics.

### Other Papers Read.

The other papers in this section, some of which were read by title, were the following: "The Origin of Sensation and Thought from an Embryologic Point of View," by Dr. J. M. Fort, Paris; "A Comparative Study of the Value of Methylene Blue and Quinin in the Treatment of Malarial Fever," by Dr. John T. Moore, Galveston; "Influenza," by Dr. J. R. Nichols, Terrell; "The Deaf and Blind and What Texas Does for Them," by Dr. M. M. Smith, Austin; "The Action and Uses of Digitalis," by Dr. S. E. Hudson, Austin; "Typhoid Fever," by S. T. Turner, El Paso; "Rheumatism," by Dr. J. H. McCracken, Mineral Wells; "Achlorhydria Gastrica," by Drs. Q. W. McLaughlin and S. M. Morris, Galveston; "Therapeutics of the Glycerophosphates," by Dr. H. A. West, Galveston.

### Obstetrics and Surgery.

Among the papers read were: "Importance of Early Recognition and Prompt Rectification of Deviations from the Normal Mechanical Evolutions of Labor," by Dr. J. F. Y. Paine, Galveston; "The Management of an Uncomplicated Case of Labor by the General Practitioner," by Dr. W. H. Munday, Terrell; "The Management of the Third Stage of Labor and Hemorrhage," by Dr. B. F. Kingsley, San Antonio; "Fever of the Puerperal State from a Surgical Standpoint," by Dr. Emory Laphear, St. Louis, and "Hemorrhoids," by James P. Tuttle, New York City. Dr. John O. McReynolds, Dallas, read a paper on "Injuries to the Eye"; Dr. James E. Thompson, Galveston, a paper on "Interseapulo-Thoracic Amputation," and Dr. E. B. Shields, Victoria, reported two cases of cranial injuries.

### Jurisprudence and State Medicine.

In the department of medical jurisprudence, "Some Problems of Texas Insane Asylums" were discussed in a paper by Dr. Martin L. Graves, San Antonio. Dr. John L. Turner, Terrell, gave a report on "The Insane and Hospital Management." "The Criminal Insane" formed the subject of a contribution by Dr. G. H. Moody, San Antonio, and in a paper entitled "School Life and Insanity," Dr. J. S. Lankford, San Antonio, made an earnest plea for the revision and classification of school tasks with the view of relieving tender brains on whom they now press with fatal effect. Dr. R. B. Sellers, San Antonio, read an essay on "The Physician as an Expert Witness," and "Subconscious Homicide and Suicide, Their Physiologic Psychology" was the subject of a contribution by Dr. Charles P. Bancroft, Concord, N. H.

In the Section of State Medicine and Hygiene, the chairman, Dr. W. S. Carter, Galveston, commented on the great progress made in recent years in preventive medicine: Dr. F. E. Daniel, Austin, delivered an address on "The Paramount Duty Texas Owes to Her People," and Dr. C. E. Lord, Galveston, who was present as the official representative of the Marine-Hospital Service, read an interesting paper on "The Influence of Flies in the Spread of Typhoid Fever."

Good programs were also presented in the sections devoted to gynecology, ophthalmology, and pathology.

### The Prevention of Tuberculosis in Texas.

Dr. W. S. CARTER, Galveston, submitted a report from a committee appointed last year to consider the possibility of securing uniform action to prevent the spread of tuberculosis in Texas. A number of recommendations were made, including one for the continued inspection of cows suspected of having the disease. In speaking of the report, Dr. Frank Paschal, San Antonio, of which city he has long been health officer, gave the association a number of statistics that he had compiled during the last thirty years. These showed that tuberculosis was increasing there, and that it had been increasing at a particularly rapid rate since the city became a health resort. It might be supposed that the additional death-rate was due to the mortality among the visitors, but this he proved was not the case. Therefore, it was necessary, he contended, to

introduce restrictions to prevent the reckless immigration of tuberculous subjects. Well-to-do consumptives could be provided for, but it was necessary to have a hospital for the indigent patients who came in large numbers to the city, and said in effect, "You must take care of us, or we will sit down on the steps of your houses and die." Many of these people did die, while others wandered from place to place scattering infection. Irrespective of commercial interests, or even from the point of view of their preservation, it was in the highest degree essential that uniform action should be taken to stop the spread of this deadliest of all infections. After further discussion it was agreed to take steps with the view of having health boards properly organized all over the state. In the meantime, as the beginning of a campaign of education, it was voted to spend \$200 in distributing literature in regard to the means that should be taken for guarding against the spread of the infection.

### New Office-Bearers.

The office-bearers for the ensuing year were elected as follows: President, Dr. S. C. Red, Houston; vice-presidents, Drs. J. E. Thompson, Galveston; Dr. J. E. Gilcreest, Gainsville, and Dr. H. K. Leake, Dallas; secretary, Dr. H. A. West, Galveston; treasurer, Dr. R. F. Miller, Sherman; orator, Dr. M. L. Graves, San Antonio. The secretary, Dr. West, was appointed delegate to the American Medical Association's meeting at Saratoga Springs, and he was given special instructions to do all in his power to induce that body to hold its next meeting in San Antonio, Texas, where the state association will meet next year.

### ILLINOIS STATE MEDICAL SOCIETY.

*Fifty-second Annual Meeting, held in Quincy, May 20 to 22.*

President, Dr. John T. McAnally, Carbondale, in the Chair.

### The Profession and the Lay Press.

Mayor Steinbach welcomed the delegates to Quincy, and the various committees made their preliminary reports. The first important paper presented was that of Dr. James W. Pettitt, Ottawa, on "What Should be the Attitude of the Medical Profession Toward the Secular Press?" in which he advised the medical profession to make legitimate use of the press, as that is the only channel through which the public can be reached. He did not consider it unethical for the profession to discuss medical topics in the secular press, nor did he believe it right to ostracize a physician simply because his name appeared in the news column of a lay journal.

Drs. WILLIAM A. EVANS and ADOLPH GEHRMAN, Chicago, presented an interesting treatise on "The Difference Between Human and Animal Blood."

### Section Addresses.

Dr. ROSWELL PARK, Buffalo, N. Y., delivered the address in surgery, taking for his subject "Surgical Intervention in Borderland Cases."

Dr. GEORGE DOCK, Ann Arbor, Mich., discussed in the address in medicine "Pernicious Anemias, Their Diagnosis and Treatment."

Dr. CHARLES B. JOHNSON, Champaign, ex-president of the State Board of Health, presented as the address in state medicine "A Country Doctor's Contribution to Preventive Medicine."

### New Constitution.

The Committee on Constitution and By-Laws presented a new constitution drafted in conformity with the plan of reorganization proposed by the American Medical Association, which was discussed, amended and adopted.

### Amendment to Constitution.

An amendment to the constitution was adopted whereby officers will be chosen in open convention instead of by a nominating committee as heretofore.

### Proposed Medical Practice Act.

At the morning session of the second day the Committee on Medical Legislation presented a medical practice act to be submitted to the session of the state legislature. This was also discussed and adopted. The bill is exhaustive and creates a

board of seven medical examiners to be appointed by the governor on the recommendation of the incorporated medical society of the state. The members of this board shall receive \$10 a day when on actual duty, and a secretary is to be appointed who shall receive a salary to be affixed by the board. The bill provides that no person shall practice medicine or surgery after Jan. 1, 1904, without a license from this board. There is no provision in the bill for licensing those who practice osteopathy, mental healing, Eddyism, etc., but these persons must also pass an examination by the board.

#### Popular Instruction in Tuberculosis.

DR. GEORGE W. WEBSTER, Chicago, president of the State Board of Health, presented a paper, "What Should We Teach the People in Regard to Tuberculosis?" This paper was of more than ordinary interest, and took the high ground that consumption is not hereditary, but an infectious disease. It will be issued in pamphlet form and circulated by the State Board of Health.

#### Annual Banquet.

The annual banquet was held at the Hotel Newcomb, May 21, Dr. Denslow Lewis, Chicago, acting as toastmaster.

#### Election of Officers.

The election of officers resulted as follows: Dr. Malcolm L. Harris, Chicago, president; Dr. Edmund W. Weis, Ottawa, secretary; Dr. James H. Stowell, Chicago, assistant secretary; Dr. Everett J. Brown, Decatur, treasurer, and Drs. Otho B. Will, Peoria, David W. Graham, Chicago, and Edgar P. Cook, Mendota, judicial council.

#### Delegates to American Medical Association.

Drs. John T. McAnally of Carbondale; Frank X. Walls, Chicago, and Henry P. Beirne, Quincy, were elected delegates to the American Medical Association, and Drs. William F. Grinstead, Cairo; Harold L. Moyer, Chicago, and Otis Johnston, Quincy, alternates. The following were also elected delegates, to serve in case the rules shall allow the state to be represented by eight: Drs. Otho B. Will, Peoria; Elijah A. Morgan, Decatur; John B. Murphy, Chicago; George N. Kreider, Springfield, and Elbert E. Clark, Danville, with the following as alternates respectively: Ernest Mammen, Bloomington; Wilbur C. Wood, Decatur; Arthur R. Edwards, Chicago; Lewis C. Taylor, Springfield, and Benjamin L. Evans, Watseka.

#### Chicago in 1903.

It was decided to hold the 1903 convention of the society in Chicago, and Dr. Arthur R. Edwards was made chairman of the Committee of Arrangements.

### NEW YORK STATE MEDICAL ASSOCIATION.

*Fifth District Branch, Eighteenth Annual Meeting, held in New York City, May 6, 1902.*

President, Dr. E. Mayer, New York City, in the Chair.

The meeting was well attended. The president delivered the annual address before taking up the routine business.

#### The Use and Usefulness of the X-Ray in Medical and Surgical Practice.

DR. WALTER M. BRICKNER opened the scientific session with this paper. He said that not only should the physician who aspires to employ the x-ray learn to develop his own plates, but he should make himself familiar with the management of vacuum tubes. That quality of a vacuum tube called "penetration" was not altogether dependent upon the degree of the vacuum, at least with new tubes, and it was very important to learn that high vacuum means poor definition, while low vacuum means dark shadows but clearer outlines. It followed that one must learn to regulate the vacuum in fluoroscopy so that, while the shadows are not too dark, the details are sufficiently clear.

#### Regulation of the X-Ray Tube.

A vacuum suitable for giving satisfactory pictures on the screen is too high for the best results with photographic plates.

Increasing experience had taught him to abandon high tubes for fluoroscopic work, and to use a very low tube, even for making radiographs. It was evident from this that the tubes should be capable of easy regulation. The most difficult task was to maintain the vacuum at a desired fixed point during an exposure. He had found that this could be done by varying the quantity of current passing through the tube. The vacuum having been once reduced to a point at which blue light showed in the bulb, a current should be passed of sufficiently high amperage to heat the target somewhat, and so offset the tendency for the vacuum to rise. By manipulation of the rheostat the vacuum could be kept down at the fixed point, or lowered or raised at will. If the electrolytic interruptor were employed, the operator could tell by the pitch of the sound emitted the degree of vacuum present.

#### X-Ray Burns.

As it was now known that x-ray burns do not occur except after unnecessarily long exposures, the operator need not be fearful, though he should still be careful. Ordinarily an exposure of from three to five minutes would suffice. The speaker then quoted a recently-published article of another x-ray worker, to the effect that it was safe to estimate that not one patient in a thousand had been injured in the past five years by the x-rays, and not one in ten thousand during the past year; also that two-thirds of these injuries had occurred in the first two years of the use of the x-ray, and that about one-third of the sufferers were x-ray workers. Dr. Brickner added that in his own work at the Mount Sinai Hospital, where several exposures were often made in succession, there had been no x-ray burns, though his own hands, from daily exposure to the rays, had been the seat of a mild dermatitis.

#### Surgical Diagnosis.

To illustrate the surgical uses of the x-ray, a large number of pictures were exhibited. One of them was interesting as illustrating a method of determining changes in the teeth and collections of pus in the antrum of Highmore. The method employed consisted in enclosing a piece of kodak film of suitable size and shape in black paper and wrapping this black envelope in a waterproof covering made of surgeon's gutta-percha tissue. The film thus protected is molded against the teeth and alveolar process, and held in place by the tongue. A short exposure was usually sufficient. Several pictures were presented to illustrate the value of the x-ray in detecting slight fractures of the bones of the foot, which would otherwise be overlooked. The speaker said that probably the simplest and best method of localizing foreign bodies in the tissues was the comparatively recent one of stereoscopic radiography, still, however, in its infancy.

#### Medical Diagnosis.

It is now generally admitted that the x-rays were of some value in studying diseases of the thoracic organs, and that here the fluoroscope was often exceedingly useful. While in most instances auscultation and percussion would give as reliable information as the x-rays, the latter method of examination was a useful means of confirming the results of auscultation and percussion, and sometimes proved of value in correcting those results. If care were taken to minimize the effects of distortion, the fluoroscope could be used advantageously to watch the effects of the Schott treatment of cardiac disease. The nipple and other landmarks should be made prominent by the use of lead wire. The most important use, however, was in the diagnosis of aneurism and of new growths within the thorax. The results of x-ray examinations of the abdomen had, for the most part, been unsatisfactory, if one might except the detection of calculi in the ureters and kidneys.

#### X-Ray Therapeutics.

On this subject, Dr. Brickner said that the x-rays could not be regarded as specific in their action on malignant growths, and that the production of a reaction was not essential to the treatment. The successes so far recorded had been chiefly with superficial growths and ulcerations, but these results should make us hopeful for the future of this work.

## Discussion.

DR. S. A. KNORF was not enthusiastic regarding the aid rendered by the *x*-ray in the diagnosis of disease of the lungs. He thought the shadows observed should only be interpreted in the light afforded by the history of the case.

DR. ROBERT NEWMAN cautioned against hasty deductions from radiographs, especially if prepared by non-medical persons. He said that the fluoroscope had decided limitations as compared with the skiagraph.

DR. W. S. GOTTHEIL said that the application of the *x*-ray was by no means innocuous. Recently an amputation in the middle of the thigh had been done in this city because of the injury inflicted by one exposure. He thought bad results were not reported nearly as frequently as they should be.

#### The Province of the General Physician in Diseases of the Upper Air Passages.

DR. D. BRYSON DELAVAN said that there should be no antagonism between specialism and general medicine. It was impossible for one person to grasp the whole of the vast science of medicine. There was much that the general practitioner could do for diseases of the upper air passages. For example, a man of middle age, of convivial tendencies, was apt to find at the end of a busy season that he was suffering a good deal at night from a general congestion of both nose and throat. These so-called lithemic disorders of the upper air passages should be recognized and appropriately treated. Such a case usually required only moderate rest and recreation, regulation of the diet, and taking of more exercise and perhaps of a few Turkish baths to effect a speedy cure. An occasional cholagogue was, of course, useful in such cases. Again, it should be remembered that, as a rule, constipation was attended by a disordered state of the circulation of the pharynx; indeed, dry pharyngitis and chronic constipation were regularly associated. A supposed lymphoid hypertrophy at the base of the tongue often disappeared under treatment directed towards relieving the disordered condition, quite probably a hyperacidity. Sometimes a person would begin to complain of a sensitive spot at the base of the tongue, or in the middle of the pharynx, and would quickly become melancholy and apprehensive, insisting that malignant disease was developing. Examination would show only a small and highly sensitive area of lymphoid tissue, probably not more than a quarter of an inch in diameter, which would usually be made worse by local treatment. Treatment of the general health, and probably an underlying gouty state, would effect a cure. The speaker said that he had been told by the surgeon of a United States schoolship that whenever that vessel is in New York harbor a large number of the boys are sick with tonsillitis, but that within two days after starting on a voyage the tonsillitis clears up. This hint should not be lost on those in charge of persons with sensitive throats.

Few diseases are more difficult to treat than those of the accessory sinuses; hence the tyro should avoid such cases. On the other hand, a skilled general practitioner could often operate successfully upon enlarged tonsils and pharyngeal adenoids requiring such treatment. Ordinarily, however, the surgical treatment of the upper air passages demanded a familiarity with a special technic which was usually only possessed by the specialist. Greater care in the treatment of an ordinary cold in the head would frequently prevent much misery and subsequent special treatment; this ounce of prevention lay in the hands of the family doctor. He would say to every physician: "If you are clearly able to do a certain thing, do it; if not, let some one else do it who can."

## Discussion.

DR. E. MAYER said that he had recently been able to follow a case of acute ethmoiditis developing in a nurse after an attack of the grip. He felt sure that many specialists would have promptly operated, and that as a result the girl would have been suffering from a chronic ethmoiditis. Instead of this he had prescribed rest and the use of soothing and mild antiseptic local applications, with the result that at the present time she was absolutely cured.

DR. A. RUPP said that unfortunately the laity are of the opinion that the specialist can do everything in his particular field and that the general practitioner knows so little about it that he should not be trusted.

DR. W. G. SCHAUFFLER, Lakewood, N. J., said that the general practitioner was largely responsible for the education of the lay public. General practitioners should not be so afraid of specialists and should not experiment for their own good on patients whom they knew could be better and more satisfactorily treated by specialists. He had found that many people were kept too long under the care of specialists in the large cities before being sent to some health resort to recuperate. Many of these persons would have done still better if the specialists had not been so enthusiastic and had left something to nature.

## Illustrations of Skin Affections.

DR. W. S. GOTTHEIL gave a lantern exhibition. One photograph was of herpes zoster of one side of the gluteal region, the perineum, the scrotum and the glans penis. This was the only case of the kind that he had ever seen. In connection with the pictures of ichthyosis he said that there were now on record two well-authenticated cases of the cure of this disease by the persevering use of sulphur ointment for from three to five years. The rather rare form of varicella, called varicella gangrenosa, was pictured. One slide showed a case of scabies in which there was a pigmentation of the skin resembling melanoderma. It was the result of long-continued scratching. Another slide showed pityriasis versicolor affecting the face of a colored boy. A second photograph showed pityriasis versicolor on the palm of the hand. This occurred in the person of a physician, and, so far as Dr. Gottheil knew, was the only case of the kind on record.

## Officers Elected.

DR. PARKER SYMS, New York City, was elected president; Dr. Charles E. Townsend, Orange, vice-president; Dr. C. S. Payne, Liberty, secretary; Dr. Edmund L. Cocks, New York, treasurer.

## CHICAGO SURGICAL SOCIETY.

*Regular Meeting, held May 5, 1902.*

Dr. Arthur Dean Bevan in the Chair.

## Laryngeal Carcinoma.

DR. BEVAN reported three cases. In the first, the disease had existed for a number of months, and radical operation was not thought justifiable. The extension to the esophagus made a tracheotomy necessary to relieve the dyspnea; as the patient could not swallow, it was also necessary to resort to rectal feeding. The case was an example of the work which had been done in the past, certainly up to the time of the celebrated case of the German Emperor. In the second case a preliminary tracheotomy was done and later the larynx was completely removed. The patient was now wearing a tracheotomy tube. He was very much improved by the operation, and was now in a condition to wear an artificial larynx.

## Perforation of the Bowel in Typhoid Fever.

DR. G. E. ARMSTRONG, of Montreal, Que., read a paper with this title, by invitation. He said that during the past six years there had been treated in the Montreal General Hospital 932 cases of typhoid fever. Perforation of the ileum had occurred in 24 cases, or 2.3 per cent. In one case of a most malignant type, with tympanites, dulled sensorium and profound toxemia, the perforation was first recognized at the autopsy. In 33 cases the perforation was recognized during life and the opening closed. Five of these recovered. In one other case the patient died five days after operation, and the pathologist reported that death was due to the typhoid toxemia and not to the perforation. If that case be included, there were 6 recoveries in 33 cases, or 18.18 per cent. As to sex, there were 21 males and 9 females. In three cases the sex was not stated. Of those that recovered, 3 were males and 3 females. The number of females in the recovery list was striking.

There were 21 males operated on and 3, or 14¼ per cent., recovered and of 9 females, 3, or 33 1-3 per cent., recovered.

#### Leucocytosis.

He had not found the presence or absence of leucocytosis a guide to be depended upon. In one case it increased 50 per cent. in the first two hours after perforation. In another case it was only 4600 eight hours after the occurrence of symptoms of perforation. In one case it increased from 4000 to 10,000 in 6 hours. He then made an exploratory incision, and found no perforation, but an apparently acute infection of the mesenteric glands. The patient made a good recovery. In another case it was only 4000 at 11 hours after perforation; 2 hours later the perforation was closed by operation, and the patient recovered. It was a symptom to be carefully observed and considered in association with the presence or absence of other symptoms, but upon which alone no great reliance could be placed.

#### Operation.

In the Montreal cases, the operation was performed during the first 12 hours in 10 cases, with 4 recoveries, 40 per cent.; second 12 hours in 10 cases, 1 recovery, 10 per cent. Of the 20 cases operated on during the first 24 hours, 5 recovered, or 25 per cent.; during the third 12 hours, in 3 cases and they all died. One case operated on 48 hours after perforation, died; another with operation 68 hours after perforation, died; 1 case, 7 days after perforation, recovered; 7 cases, time after perforation uncertain, died. Of the 6 recoveries, one was operated on 2 hours after the perforation, one 13 hours after, one 8 hours, one 10 hours, one 5 hours, and one 7 days after. The operation in the last case was really nothing more than the opening of an intra-abdominal abscess. Of the 5 acute cases, 4 were operated on during the first 12 hours. So far as his experience goes, it indicates early interference.

#### Discussion.

DR. FRANK BILLINGS said that perforation of the intestine in typhoid fever occurred in practically 3 per cent. of the cases. The severity of typhoid fever in its clinical course bears no relation to perforation. For instance, those who have the disease in mild form are just as likely to have perforation of the intestine as those who are very sick. Furthermore, the number of ulcers in the intestine bears no relation to the height of the fever or to the severity of the general course of the disease. A patient with typhoid fever might become as deeply toxic from a single as from numerous ulcers of the intestine. He regarded pain as one of the main springs of diagnosis in typhoid perforation. Pain might be due to inflammation or infection of the mesenteric glands. These might rupture. In that event, it was practically the same as a rupture of the intestine which required operation. He emphasized the importance of leucocytosis in typhoid fever cases, and if blood counts are taken sufficiently often he thought they might prove of great value. The earlier an operation is performed in cases of perforation of the gastro-intestinal tract, the greater the chance for recovery of the patient.

DR. N. B. CARSON, St. Louis, thinks that many local abscesses form in the lumbar region. We have also so-called psoas abscesses. He has often been impressed that perforation sometimes takes place between the folds of the mesentery and burrows back, forming local abscesses.

DR. E. WYLLYS ANDREWS narrated a successful case and favored early operation.

DR. ALEXANDER HUGH FERGUSON mentioned a case on which he operated for a supposed appendicitis. The patient, while convalescing from typhoid fever, was seized with severe pain in the region of the appendix. A tumor developed and proved to be an abscess which had communicated with the bowel.

D. L. L. McARTHUR reported three unfavorable results in fairly early operations. Notwithstanding, he believes that the only proper course is operation as early as possible.

DR. M. L. HARRIS detailed a case with evidences of acute cholecystitis. In examining the blood, he found leucopenia. The absence of the characteristic granules and other evidence suggested typhoid. A Widal reaction was positive, and the case was treated as one of typhoid fever.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

#### To Prevent Puerperal Convulsions.

T. H. Ross, as noted in *Med. Standard*, emphasizes the importance of maintaining the function of the liver during pregnancy. He thinks that the functional errors of the stomach, liver, etc., lead often to an obstinate constipation, which in turn increases the toxemic condition and the danger. By regulating the liver and maintaining its tone and highest working capacity much discomfort and many ills can be prevented throughout the puerperium, especially that worst of all complications, puerperal convulsions. He advises, in addition to the correct hygiene and dietetics of pregnancy, that the patient be given the following pill once daily.

|                               |          |     |
|-------------------------------|----------|-----|
| R. Enoymin .....              | gr. 1/8  | 008 |
| Hydrarg. chloridi mitis ..... | gr. 1/8  | 008 |
| Pulv. ipecacuanhæ .....       | gr. 1/8  | 008 |
| Aloin .....                   | gr. 1/12 | 005 |
| Podophyllin .....             | gr. 1/20 | 003 |

M. Ft. pilula No. i. Sig.: One such pill at bedtime.

The amount of the foregoing combination suitable for a given case must be determined by a few nights' use. The best rule is to give enough to cause one natural movement of the bowels daily. If one pill is too much, give a fraction; if too little, double the dose. When there is no indication of auto-toxemia it may be given by the above rule, alternate fortnights for months, with benefit to both mother and child in a general way, until the lying-in period is fully accomplished, and even later it will assist in involution and the return to the ordinary conditions of life.

#### Oxyurides.

The following is recommended by *Med. Orientale* in the treatment of seat worms:

|                          |           |    |
|--------------------------|-----------|----|
| R. Ung. hydrarg. ....    | gr. iss   | 10 |
| Adipis benzoïnatis ..... |           |    |
| Ceræ albæ, āā .....      | gr. viiss | 5  |
| Ol. theobrom. ....       | 3ss       | 2  |

M. Ft. suppositorium. Sig.: One such to be inserted daily.

#### Dentition.

The argument that dentition is a purely physiologic function and therefore can not cause pathologic phenomena is regarded by W. J. Robinson, in *Merek's Archives*, as untenable. When the gums are hot and tense, then frequent rubbing with the following combination will give proper relief:

|                            |         |      |
|----------------------------|---------|------|
| R. Potassii bromidi .....  | gr. xx  | 1/30 |
| Chloralis hydratis .....   | gr. x   | 65   |
| Tr. aconiti rad. ....      | m. v-xv | 30-1 |
| Spts. chloroformi .....    | 3i      | 4    |
| Mucilaginis q. s. ad ..... | 3i      | 30   |

M. Sig.: Apply to the gums frequently by rubbing.

At the same time he recommends that the following be given internally:

|                            |           |       |
|----------------------------|-----------|-------|
| R. Pot. bromidi .....      | gr. iii-v | 20-30 |
| Chloralis hydrates .....   | gr. i-ii  | 06-12 |
| Aq. destil. q. s. ad ..... | 3ii       | 8     |

M. Sig.: To be given at one dose by the mouth.

The foregoing mixture may be given in double the size dose per rectum, using starch water as a vehicle.

#### Diet in Epilepsy.

Davis, in an article on the diet in epilepsy in the *Sys. of Phys. Ther.*, states that the epileptic should be abstemious. Unfortunately, the tendency is to overeat. Epileptics should be taught the relationship between the digestive disorders or constipation and their ailment. Sweets should be avoided. Meat should be restricted to once a day and then in small amounts. The most important thing is the restriction of the

amount of food and the limitation of the variety to those articles that are easy to digest and to absorb. He gives the following sample menu for a day of the epileptic colony at Chelfont St. Peter: Breakfast, oatmeal porridge with new milk, tea, bread and butter; dinner, roast or boiled or hashed beef, mutton or fish, cabbages and potatoes, followed by rice, sago, tapioca, suet or jam roll pudding, tea with bread and butter or dripping or sometimes golden syrup or currant cake; supper, some pudding generally with milk and bread, varied occasionally with soup.

### Erysipelas.

In the same journal Dr. Robinson recommends the employment of ichthyol in the treatment of erysipelas. In the mild cases, judging by the exterior extent of the inflammation, the temperature and general constitutional symptoms, the following should be employed:

|                           |      |    |
|---------------------------|------|----|
| R. Ichthyol .....         | 3i   | 30 |
| Adipis lani q. s. ad..... | 3iii | 90 |

M. Sig.: To be applied every hour.

In severe cases, the entire area of inflammation and about one inch beyond should be painted with pure undiluted ichthyol. Outside of this gauze compresses soaked in a 10 to 20 per cent. solution are to be applied every hour. The solution is made as follows:

|                   |        |       |
|-------------------|--------|-------|
| R. Ichthyol ..... | 3i-3ii | 30-60 |
| Glycerini .....   | 3i     | 30    |
| Aq. q. s. ad..... | 3x     | 300   |

M. Sig.: Apply locally on gauze every hour.

The glycerin prevents too rapid drying of the solution and cracking of the skin. Although the pure ichthyol will cause the skin to peel off, yet antipyretics have never been employed when the case has thus been treated from the beginning. The writer, however, employs throughout the course of the disease a saline laxative as follows:

|                               |         |      |
|-------------------------------|---------|------|
| R. Mag. sulphatis .....       | 3i      | 30   |
| Acidi sulphurici dil. ....    | m. xxiv | 1 65 |
| Syr. limonis .....            | 3i      | 30   |
| Aq. menth. pip. q. s. ad..... | 3iv     | 120  |

M. Sig.: Take one tablespoonful every two to four hours as necessary to produce a laxative effect.

### Prevention of Oxalic Sediment in the Urine.

G. Klemperer, in *Prog. Phys. Ther.*, suggests a diet which excludes milk, eggs, tea, cocoa and most vegetables, and embraces meat, fats, bread, flour foods, rice, leguminous vegetables, apples and pears. These latter, according to his statement, contain considerable calcium and magnesium, with a minimum of oxalic acid.

### Scarlet Fever.

W. T. Corlett, in the *Med. News*, recommends that a tepid sponge bath be given twice a day, followed, when there is itching or desquamation, by inunction from head to foot with cold cream, carbolyzed vaselin, lanolin, cocoa butter or eucalyptus oil. The following is recommended for the throat:

|                      |          |      |
|----------------------|----------|------|
| R. Menthol .....     | gr. ii   | 12   |
| Thymol .....         | gr. 1/10 | 0065 |
| Ol. gaultheria ..... | m. ii    | 12   |
| Glycerini .....      | 3iv      | 15   |
| Aque q. s. ad.....   | 3viii    | 240  |

M. Sig.: Use as a spray or gargle.

Cracked ice or irrigation with hot water to which glycerin has been added promotes the comfort of the pharynx. The best antipyretic is cold water, or occasionally quinin or phenacetin, or the cold pack.

The following combination containing iron should be given:

|                                |      |    |
|--------------------------------|------|----|
| R. Tinct. ferri chloridi ..... | 3ii  | 8  |
| Acidi hydrochlor. dil. ....    | 3i   | 4  |
| Syr. limonis .....             | 3i   | 30 |
| Aque q. s. ad.....             | 3iii | 90 |

M. Sig.: One teaspoonful every two or three hours; or:

|                           |       |     |
|---------------------------|-------|-----|
| R. Liq. ammon. acet. .... | 3iiss | 45  |
| Potassii chloratis .....  | 3i    | 4   |
| Syr. limonis .....        | 3ss   | 15  |
| Aque .....                | 3vi   | 180 |

M. Sig.: One to three teaspoonfuls every three or four hours.

### Orchitis.

Lutaud, according to *Medicine*, combats the pain of orchitis by the administration of cachets containing seven and a half grains of quinin sulphate. In the majority of cases pain is arrested after the first dose and it is unnecessary to give an injection of morphin. At the same time the following is applied locally:

|                             |     |    |
|-----------------------------|-----|----|
| R. Methyl salicylatis ..... | 3vi | 24 |
| Guaiaicol .....             | 3i  | 4  |
| Vasellini .....             | 3i  | 30 |

M. Sig.: Apply locally once or twice a day.

### To Prevent Pitting in Smallpox.

T. C. Gibson, in *Medicine*, recommends the following as a superior combination in preventing pitting in smallpox:

|                     |     |    |
|---------------------|-----|----|
| R. Ichthyol .....   |     |    |
| Guaiaicol, aa ..... | 3ii | 8  |
| Glycerin .....      | 3ss | 15 |

M. Sig.: Apply locally with a feather three times a day. He states that the earlier it is commenced, the better the effect. The face should be bathed with warm water and soap previous to each application.

### Malarial Attacks.

Regnault, as noted in *Ther. Monthly*, states that he successfully treats malarial attacks with a mixture of iodine and potassium iodid as follows:

|                       |      |    |
|-----------------------|------|----|
| R. Tinet. iodi .....  |      |    |
| Pot. iodidi, aa ..... | 3i   | 4  |
| Aq. destil. ....      | 3iii | 90 |

M. Sig.: Take one tablespoonful at the beginning of the attack and repeat if necessary in twenty minutes. In the cases of irregular malarial fever it is to be considered, according to the author, as a substitute for quinin.

### Administration of Quinin in Children.

It is necessary in administering quinin to children, in most instances, to mask the bitter taste and otherwise make the preparation as palatable as possible. The following combinations employed by Lemanski, as reported in *Pediatrics*, are recommended:

|                            |         |    |
|----------------------------|---------|----|
| R. Quinina sulphatis ..... | gr. x   | 65 |
| Aque (acidulated) .....    | m. lxxv | 5  |
| Mellis despumati .....     | 3x      | 40 |

M. Sig.: One coffee-spoonful every two or three hours; or:

|                             |          |    |
|-----------------------------|----------|----|
| R. Quinina hydrochlor. .... | gr. ivss | 25 |
| Ext. glycyrrhizae .....     | gr. xlv  | 3  |
| Aq. destil. ....            | 3x       | 40 |

M. Sig.: To be taken at one dose.

The *Klin. Ther. Woch.* gives the following combination:

|                           |       |    |
|---------------------------|-------|----|
| R. Quinina sulph. ....    | 3i    | 4  |
| Acidi citrici .....       |       |    |
| Syrupi .....              |       |    |
| Syrupi aurantii, aa ..... | 3iiss | 10 |
| Aq. destil. ....          | 3v    | 20 |

M. Sig.: Ten drops to be added to two tablespoonfuls of water and taken at one dose. Sodium bicarbonate may be added and the mixture drunk while effervescing. Dr. Lemanski sometimes prefers the rectal method of administration, the suppository being better tolerated than the enema and causes no smarting or defecation. The following combination may be employed:

|                         |               |      |
|-------------------------|---------------|------|
| R. Quinina sulph. ....  | gr. iss-viiss | 09-5 |
| Olei theobromatis ..... | gr. xv-xlv    | 1-3  |

M. Ft. suppositorium. Sig.: Insert two daily. In some cases the cocoa butter may be replaced by glycerin solidified by the addition of gelatin.

## Medicolegal.

**Recovery for Physical Injuries Caused by Fright.**—The Supreme Court of Iowa says, in the case of *Watson vs. Dilts*, that many cases have been before the courts in which the question of a recovery for mental pain alone, and for physical disability produced by fright, unaccompanied by physical impact, have been decided; and the decisions on these questions are in

conflict, though it is probably true that the numerical weight of authority denies the right of action. But the cases so holding are not in harmony as to the reasons given for denying the right of action; some of them hold that the injury is not the proximate result of the alleged negligent or wrongful act, while others refuse a recovery for the reason that it is practically impossible to satisfactorily administer any other rule and serve the purposes of justice. A large majority of the cases which hold to the doctrine that no recovery can be had are cases in which the simple charge of negligence was made, and in many of them no claim was made for physical disability resulting from the fright. In this case, the person sued for damages stealthily invaded the home of the party suing in the night time. When he entered and went to an upper room, she did not know who it was, nor his purpose and intent in thus breaking in. She called to her husband to follow him, which he did; and, in her apprehension of danger, she followed her husband up to a room, where she found them in what appeared to be an encounter, and an assault upon her husband. From her great fright thereat, she averred that her nervous system completely gave way, and that she suffered physical injuries from the fright. The court says that its attention has not been called to any case where the facts averred precisely paralleled those in this case, nor has it discovered anywhere the facts alleged so strongly condemn the unlimited rule contended for that no recovery can be had for physical injuries caused by fright. The object of the invasion of the home in such manner was immaterial. Suppose that the object was to ransack the house, and steal therefrom; that the man went in masked, and with a deadly weapon in his hand. His discovery there under such circumstances might well cause alarm to the boldest man, and, if it produced nervous prostration and physical disability, the theory, no matter what its reason, that would say there was no actionable wrong, the court says, would be too fine spun and too cold for its sanction. Nor could it be said, under such circumstances, that the prostration resulting from the fright so caused was not the proximate or probable result of the party's act. It is within the common observation of all that fright may, and usually does, affect the nervous system, which is a distinctive part of the physical system, and controls the health to a very great extent, and that an entirely sound body is never found with a diseased nervous organization; consequently, one who voluntarily causes a diseased condition of the latter must anticipate the consequence which follows it. The nerves being, as a matter of fact, a part of the physical system, if they are affected by fright to such an extent as to cause physical pain, it seems to the court that the injury resulting therefrom is the direct result of the act producing the fright. But each case must, of necessity, depend on its own facts.

**Evidence Derived from Tests of Extent of Injuries.**—In *Missouri, Kansas & Texas Railway Company of Texas v. Johnson*, a personal injury case brought by the latter party, a bill of exceptions showed that a physician was introduced as a witness in this party's favor, and testified that about six months before the trial he had examined him for the purpose of ascertaining the nature and extent of his injuries, not for treatment, but only in order to qualify himself to testify as an expert in the trial; that on such examination the party complained of suffering considerable pain in certain portions of his back and, when the witness would stick pins into him along his right leg, he would exhibit no signs of suffering pain, but when he would stick pins into him at corresponding places on his left side, he would flinch and complain a great deal. The Court of Civil Appeals of Texas thinks that it must be held that the complaint of the party was the natural expression produced by the pain then existing, and that, this being so, the complaint was part of the *res gestæ* or essential circumstances of the transaction, and not hearsay, and that the objection to it that it was self-serving could not be sustained. Likewise, it holds that the testimony of the physician to the effect that he stuck pins into the party's right leg, and that he showed no signs of suffering pain, was properly admitted. It says that the party had a right, even pending the

litigation, to have all proper examinations and tests made to ascertain the nature and extent of his injuries, and the result thereof could be proven on the trial. This was the matter under investigation, and how the party bore the tests was a part of the transaction and clearly admissible. It was a question for the jury to decide, in the light of circumstances shown to have attended the experiment, whether his indifference to pain was simulated. No statement of his that it did not hurt him to stick pins into his right leg was admitted. Only the negative fact that he did not flinch when the test was applied went to the jury, and it was not error to admit such evidence. The testimony of the physician that when he stuck pins into the party's left leg he flinched and complained of pain simply tended to show a normal condition of that part, a fact which would have been presumed without such test and proof. Whether this was a necessary part of the transaction—that is, of the examination—might be doubted, but it could hardly have been injurious to the company. The Supreme Court of Texas affirms the judgment in favor of the party suing. It does not, however, directly pass upon the points above decided because it does not consider the objections taken at the proper time, having been made before the evidence objected to was introduced. That the mere declarations of a party suing of the fact of his suffering pain, made to an expert, on an occasion prepared by himself, for the sole purpose of furnishing the expert with information on which to base an opinion favorable to him, are not admissible, it says, is held by many authorities which seem to be better supported by reason than those taking a contrary view. But the authorities referred to admit that exclamations, shrinkings, and other expressions of a party which appear to be the instinctive or spontaneous betrayal of pain are admissible, although they be made under circumstances such as those disclosed here. Nearly all of the statements of the physician of the acts and expressions of the party suing, it adds, belonged to this class, and the manner in which his evidence was stated in the statement of facts made it doubtful if the declaration of pain in the back was not produced by manipulations or tests applied by the physician.

3. **Bright's Disease.**—The question of the surgical treatment of Bright's disease is discussed by Guiteras, who reviews the literature, more especially the recent article of Elebohl, and concludes: 1. That nephropexy is a beneficial procedure in a movable kidney in a patient suffering from chronic nephritis; 2, that nephrotomy has proved valuable in unilateral chronic nephritis associated with hematuria and nephralgia; and 3,

that the value of a complete decapsulation of the kidney as a therapeutic measure in chronic Bright's disease has not as yet been determined.

6. **Hematoporphyrinuria.**—In this case, reported by Tyson and Croftan, which was due to the excessive use of sulphonal, about one-seventeenth of the hemoglobin in the body was destroyed and wasted in the urine during twenty-four hours, in the form of hematoporphyrin. We can understand how such a loss of blood pigment sustained for a prolonged period must necessarily lead to severe anemia, but in this case, fortunately, the sulphonal was stopped in good time for blood regeneration to occur.

10. **Lachrymal Reflex.**—Spiller calls attention to this reflex which consists in the secretion of tears produced by irritation. The preservation of the tear reflex in the conjunctiva in hysteric anesthesia has been observed by others, and he reports two cases where it may have been of assistance in the diagnosis.

11. **The Vermiform Appendix as a Gland.**—Killbourn points out certain anatomic and physiologic reasons for suspecting the glandular action of the vermiform appendix, both in its normal and pathologic condition, and suggests that it should perhaps be considered as of some little importance in the economy.

14.—See abstract in THE JOURNAL of February 1, p. 472.

15. **Frequency of General Paresis.**—Wagner gives a considerable portion of his paper to a review of the literature in regard to the increase in the frequency of paresis and concludes that general paresis forms about 8.75 per cent. of all cases of insanity; that it occurs most frequently between the ages of thirty and fifty; that it is gradually increasing in frequency at the present time; that men are about seven times as liable to the disease as women; that it is invariably fatal in its termination, usually so in less than two and a half years; that it is nearly twice as frequent in large cities as in the country, that heredity, syphilitic infection and alcoholic indulgence are important factors in its production; that neither the members of the learned profession, teachers, students, musicians nor actors, appear to be especially susceptible, nor does intellectual work or any other special kind of occupation seem to predispose the individual to paresis, but that general cerebral strain with more or less hereditary influence is found to have existed in the majority of cases. Overwork, sexual excesses, alcoholism, irregular habits of sleeping and eating and such accidents as sunstroke and cerebral traumatism appear to be the great factors in the production of this disease. From all his study of records he has found but a single instance of alleged recovery from the disease.

19. **Weighted Vaginal Speculum.**—Griffith reports a case in which the use of the weighted vaginal speculum seemed to have produced a sloughing, and he calls attention to the importance of warning against the use of such weighted instruments for any length of time in cases in which pressure opens the way for the assaults of infection.

22. **Stab Wounds of the Abdomen.**—From a review of the cases here reported Bissell considers the following conclusions warranted: A stab wound involving the peritoneal cavity is frequently followed by recovery without operation. In every case the wound, and the field near it, should be thoroughly antiseptized and kept so; an examination should be made with the cleansed fingers, if at all, and only to determine whether the wound penetrates the abdomen, and to ascertain if any injury has been done to the contents. If doubt exists about involvement of the organs it is better to bring the divided edge of the peritoneum into the wound, fasten it there, drain and wait. If the abdominal viscera have certainly escaped damage, the wound should be closed by suturing the peritoneum, the muscles, and the skin and fascia in three different layers, catgut being used; or if the wound be long and gaps, a catgut running suture may be used for the peritoneum and silkworm in one layer for the skin and muscles. If there be grave doubt and the symptoms point to damage in the peritoneal cavity, the wound must be enlarged and a complete ex-

ploration made carefully; or, better still, a median laparotomy may be done exactly as in an examination of tumors of the abdominal cavity. The contents of this cavity should be examined, repaired, if necessary, and returned, and the opening then sutured as before advised; or, if the damage be too severe, the injured gut or omentum should be brought to the wound and a drain inserted, in order that an exit may be given for a fecal fistula, if that misfortune happen. This last technic is similar to an operation for appendicular abscess or suppurative appendicitis. If the gut is cut across, it must be united in any one of the usual ways. If the omentum is cut off from its intestine, so much of the intestine as is deprived of its blood supply must be resected. If symptoms of internal hemorrhage are present and increasing the indication is imperative to open the abdomen, find the origin of the bleeding and control it.

**23. Pneumonia.**—According to Tuthill the most rational mode of treatment of pneumonia would be to employ internal antiseptics, which, upon being brought into contact with the bacilli through the medium of the blood, may be enabled either to destroy them or at least to embarrass their growth and development and check the influence of their poisons. He has had very good results with salol given in the first stage; 10 gr. every two hours in adults seemed to work well, widening the intervals as the symptoms subsided. Several cases are reported.

**24. Sequelae of Measles.**—Rupp reviews the clinical sequelae of measles, such as stomatitis, gangrene, diphtheria, lung disorders, cholitis, intestinal catarrh, gangrene of the genitals, rheumatic disorders, tuberculous glandular enlargement, nervous disturbances, etc., and finds the serous membranes rarely affected and the endocardium and pericardium still more rarely. There seems little in the way of blood changes so far as known. In mild cases, according to Cabot, no changes occur, but in the toxic attack of measles it is sometimes affected, losing at least some of its coagulability.

**27. The Cargile Membrane.**—Morris has received from Dr. Cargile, of Bentonville, Ark., a package of what he called "sterilized animal membrane" consisting of a peculiar thin gold-beater's skin subjected to heat-cumol sterilization, prepared in the form of a folded sheet in a sealed paper package. He has employed it in certain cases with advantage, but he gives here the details of experiments on rabbits. In only one was there any suppuration, and there it was intended that it should occur. He says it resisted absorption in the peritoneal cavity for more than ten and less than thirty days. Its presence apparently causes the formation of temporary loose adhesions, which are harmless, and which become absorbed for the most part in less than thirty days. The membrane seems to cause very little disturbance to the peritoneum, it does not furnish a good culture medium for bacteria, and it protects areas of peritoneal surface that have suffered injury to their endothelial covering, until new endothelial cells have repaired the injury without involving neighboring peritoneum. It is not necessary to suture the membrane in place, as it becomes instantly adherent to moist surfaces, and is not readily dislodged afterward. In this connection it may be well to give warning against handling the material with wet hands or instruments. In addition to the experiments in the peritoneal cavity, he has applied the membrane for a variety of purposes in wound treatment. As an animal membrane it seems to be particularly agreeable to the tissues of open wounds. It serves as an excellent conductor of epithelium when placed next the wound beneath absorbent dressings. It is not impervious to moisture, and in that regard possesses advantages over gutta-percha tissue or silver foil. In brain surgery the membrane adheres closely to exposed brain tissue, and it makes a very good dura mater for temporary purposes. It can be used to keep severed and sutured tendons from uniting en masse. He has had no opportunity to employ the Cargile membrane in plastic eye surgery, as few of these cases get to his clinics, but from our knowledge of the value of this material as a conductor of epithelium and of endothelium it would seem to offer advantages in this special field.

**29. Amaurosis.**—Derby relates a number of cases of optic nerve atrophy treated with strychnia injections in gradually increasing doses, and in about 30 per cent. with fairly encouraging results. He thinks the following conclusions are justified: 1. Strychnia is a stimulant to the optic nerve. Even in normal eyes it slightly increases the acuteness of vision and widens the visual field. These effects are temporary (Fuchs). 2. In certain cases of optic nerve atrophy its local subcutaneous injection has, to say the least, coincided with an arrest in the progress of the disease, and has been followed by a somewhat increased acuteness of vision. Whether these effects are temporary or permanent, time and fuller statistics will show. 3. In a progressive case of this disease it is clearly our duty to state the above facts to the patient, and allow him to take the treatment if he is so inclined. 4. The strychnia should always be administered in the temple, and by subcutaneous injection.

**30. Ear Disease and Life Insurance.**—The importance of ear disease in connection with life insurance examination is insisted on by Hammond, who maintains that we should not consider the patient's statements or recollections, because it may happen that suppuration has occurred in early infancy and has been forgotten or the patient may have become so accustomed to it as not to consider it a diseased condition or inconvenience. The examiner should always be on the alert. He points out that consumption may sometimes be detected by the clinical appearances in the ear, and he insists on the importance of not considering merely the chronic cases. Among the things we may put on our dangerous list are suspicious nodules or tumors of the auricle in elderly persons and ulcerated areas which may be due to breaking down of an epithelioma. Another point which seldom receives attention is the liability of persons suffering from partial deafness to accident. Vertigo may depend on various conditions, but it may favor accidents and should be a cause for careful examination. Many cases of otorrhea are easily cured, and this fact should also be considered. The prognosis is improved in late years. We should consider the rights of the applicants as well as those of the company we are safeguarding.

**33. The Future of Obstetrics.**—Hirst thinks that gynecology as a specialty is likely to wane with advances in obstetrics. The number of cases especially calling for it will lessen and the general surgeon will encroach more and more on its field. A feature of importance will be for the expert obstetrician to confine himself to such cases as promise to be unusually difficult or complicated and make his daily work the diagnosis and treatment of diseases of women, almost all of which must be studied in their relation to parturition. This is the actual condition on the continent of Europe and it must be the outcome of the shifting of work at present observable in America. The future trained nurse, he thinks, will be competent to take charge of the average labor case, the physician being only called in to repair the injuries of childbirth, or deal with any complications or abnormalities that may arise and make the daily routine visit, and above all to make the careful final examination at the end of the puerperal convalescence. By this plan the specialist and the general practitioner, too, could undertake the supervision of an almost unlimited number of cases.

**34. Uterine Prolapse.**—Beyea reports a case of prolapse of the uterus in a nulliparous woman and has collected a number of cases in the literature. The only conclusion to be gained is that commonly its subjective etiology is chiefly dependent: 1, on poor health, physical weakness and general tissue relaxation; 2, frequently on want of development of the uterus and its supports. The exciting causes are the diseases, laborious occupations and great physical effort which actively increase the abdominal pressure. The treatment naturally consists of attention to the general health and the performance of such plastic and abdominal operations as will restore the equilibrium.

36.—See abstract in THE JOURNAL of February 8, p. 412.

**43. Work in Hysteria and Neurasthenia.**—The value of employment in the treatment of hysteria and neurasthenia is dwelt upon by Schwab, who quotes from Monnier, also giving

his conclusions. By means of manual work, hysteria and neurasthenia can often be made to completely disappear. In cases of mental enfeeblement, psychopaths and alcoholics, the influence of work is often very remarkable. Hypochondriacs and paranoiacs are not specially benefited. A valuable point is the impulse which it gives to the acquirement of some definite work which may afterwards be made self-supporting.

**52. Ankle-Clonus.**—Mitchell has recently noticed the fact that in ordinary ankle-clonus the soleus alone is active, though the gastrocnemius is frequently mentioned in text-books as being also active. He points out that this can be readily shown by the perceptibly inactive condition of the gastrocnemius in flexion of the leg and the actual contraction of the soleus during the process. He explains the peculiarity by the fact that the soleus and gastrocnemius have rather distinct functions, the gastrocnemius being relaxed and inactive during the process, while the soleus is still capable of extending the foot. For all the slighter acts of extension the soleus alone is used.

**53. Two Unusual Forms of Clonus.**—Mitchell describes two types of clonus which are apparently new, viz., the lateral clonus movement of the ankle entirely in one plane and the toe clonus. Both were observed in a case of disseminated sclerosis under his charge. Theoretically, any muscle may exhibit the phenomenon, which is only a rapidly renewed contraction induced by sudden overstretching, but the ankle and wrist clonus are the only forms of this reflex that are of diagnostic value and they are not always pathogenic signs.

**55. Primary Degeneration of the Pyramidal Tracts.**—Spiller reports the case of a woman 50 years of age having a sudden weakness in the left arm, with loss of speech. The latter was partially regained in a day or two, and the weakness almost entirely disappeared after a few weeks. Two years after this attack she noticed that she was weak in the legs, and this gradually increased until it made walking difficult. All the reflexes were exaggerated; the Babinski reflex was obtained. The gait was not decidedly spastic. The right arm was not distinctly paretic, but the left was a little weak. There were no special sensory disturbances. The reaction of the irides was sluggish. The left side of the face was slightly paretic, but the right was probably also abnormal. At the autopsy the degeneration of the pyramidal tract was found extending as high as the pons, but not above this and less intense in the anterior pyramids than in the spinal cord, and was equal on the two sides of the cord. The other tracts were normal. There was no meningitis present. Some of the smaller vessels of the cerebral pia were thickened, which was not remarkable at her age. The cell-bodies of the anterior horns of the cord were in part diseased, and the nuclei of the hypoglossal nerves were probably not normal. A number of features of the case are discussed as peculiar and hard to explain. The author points out its differences from the ordinary amyotrophic lateral sclerosis, which he is inclined to think is less rare than supposed. He has found by the method of Marchi that the ascending frontal convolution is more degenerated in cases of this disease than the ascending parietal, which is interesting as compared with the results obtained by Schaffer in his study of brains from cases of paretic dementia. These studies seem to show that the motor functions are represented in the ascending-frontal convolution much more than in the ascending parietal one.

**64. Thoracic Injuries.**—After reporting cases of rupture and of penetrating wounds of the lung, Le Bontillier discusses the conditions, reviewing the opinions of others, and concludes that operative interference in thoracic injuries involving the lung is not only justifiable, but imperative: 1. In distending pneumothorax from whatever cause. If aspiration or the introduction of a trocar does not give relief, thoracotomy should be done and the lesions thus ascertained treated in appropriate ways. 2. In large hemothorax in cases of fractured ribs, contusions of the thorax without external wound and penetrating wounds of the thorax without regard to the nature of the weapon producing the injury. 3. In extensive and progressive subcutaneous emphysema after thoracic injuries. The nature

and extent of the measures to be resorted to must be determined according to the needs of the particular case. Exploratory operations may be proper in order to determine whether wounds in the lower part of the thorax have penetrated the diaphragm or peritoneum, or to satisfy one's self as to the integrity of the heart or pericardium as well as of the internal mammary or intercostal arteries; or to provide proper drainage in wounds where infection is suspected. Delorme pointed out that in penetrating wounds with pneumothorax or hemothorax the fear of causing collapse of the lung is baseless, as the collapse has already occurred. We have at hand valuable and trustworthy means of combating shock and loss of blood in the intravenous or subcutaneous injection of hot salt solution. Oxygen inhalations and strychnin are also of great value in improving the circulation and respiration. The surgeon who hesitates to open the pleura in traumatic cases for fear that he may infect should promptly improve his methods. He who can open the peritoneum or meninges safely need have no fear of infecting the pleura.

66.—See abstract in *THE JOURNAL* of January 4, p. 52.

**69. Hour-Glass Stomach.**—Elder reports a case of hour-glass stomach relieved by the performance of gastropasty, by making an incision on the anterior surface of the stomach extending from the center of each half of the hour-glass through the fibrous central ring. As the mucosa looked healthy the edges of the incision were sewed up in a direction at right angles to the primary line of incision, leaving a fairly normal looking stomach and an opening that would admit three or four fingers at ease. The results were in every way satisfactory. He remarks that the case is very similar to one published by Childe in which a gastro-enterostomy was performed, but failed to give relief, and the true condition was found at autopsy. He believes that we should make in all cases a very careful examination of the stomach before performing gastro-enterostomy and that gastropasty, where possible, is decidedly preferable in cases of non-malignant hour-glass stomach. All the literature points to cicatricial contraction following gastric ulcer as the cause of the condition, this contraction being in the stomach wall itself or the result of adhesion to the neighboring parts with subsequent stretching of adhesive bands and the contraction of the viscera.

**73. Trephining.**—Aldrich reports two cases of trephining for intracranial disease, one cured and the other markedly benefited, though in neither was a lesion found nor were the operations made over areas which the symptoms suggested might be diseased. He remarks on the puzzling nature of the case, and concludes that the trephining operation probably produces two distinct effects: 1. Relief from intracranial pressure. 2. a marked psychic effect. While it is unsafe to advise the trephine for some cases, nevertheless in those presenting evidence of cerebellar pressure, fulness of the head, headache, dizziness, staggering gait, etc., the trephine, without opening the membrane, may be of possible service.

**74. Spina Bifida.**—The following are Knott's conclusions: 1. Owing to the distressing nature of the affliction, the high mortality should not prevent attempts at surgical relief. 2. Meningoceles, meningo-myeloceles, and syringomyeloceles may be considerably benefited by operation. 3. The improvement in function can not with certainty be estimated before operation, and pronounced evidences of nervous disturbance are not a contraindication to excision. 4. Asepsis is absolutely essential, and, though difficult to secure, may be maintained by exercising extreme care. 5. The plan of having the suture lines of the meninges and the overlying tissues on different planes will, in the majority of instances, prevent leakage of cerebrospinal fluid. 6. The suggestion of Pearson, to prevent the escape of this fluid during a prolonged operation by stuffing the canal with gauze, is valuable. 7. Large bony defects may be effectually closed by muscle much easier than by osteoplastic methods. 8. It is not necessary to keep the child off his back during the healing of the wound, as frequently advised. 9. Children with hydrocephalus accompanying spina bifida should not be subjected to operation.

79. **Plimmer's Bodies.**—Le Count concludes that there is an analogy between Plimmer's bodies in cancer cells and certain structures in the cytoplasm of normal cells and that we should require advocates of the theory that they are essential to cancer to exclude or account for the centrosome and the enveloping variously named formations of the archoplasm in carcinoma cells.

83. **Food Intoxication.**—Ohlmaecher reports cases of an epidemic which occurred at the Ohio Hospital for Epileptics at Gallipolis in which 218 patients became acutely ill with symptoms of food intoxication and gastro-intestinal infection. The diagnosis being made by exclusion, the infected food was found to be a certain batch of oatmeal which had been contaminated by the dust of a ceiling from which a section of plaster had been removed. The ceiling had been exposed to the dust from the dusty road which had lodged on the moist ceiling. Living bacteria were found, among them *Bacillus coli communis* and the *Proteus vulgaris*. These were considered to account for the condition. Experimental evidence in favor of the theory is adduced.

88. **Tetanus and Vaccination.**—McFarland reviews the subject and holds that tetanus bacilli can infect vaccine virus through the manure and hay of stables and greater care is required in the preparation to avoid the complication of tetanus.

92. **Extra- and Intra-Uterine Pregnancy.**—Zinke first reports a case of extrauterine pregnancy coincident with a normal pregnancy. Celiotomy was performed, the uterine pregnancy was uninterrupted and labor occurred at term. He discusses the various questions suggested by such cases, the occurrence of the two conceptions which in this case he thinks were simultaneous, the cause and time of death of the ovum, the difficulties of diagnosis and the frequency, cause and duration of these conditions and their treatment. He thinks it one of the rarest complications of pregnancy and no pathologic conditions should be held responsible for it. The duration varies. Generally both pregnancies are interrupted, but cases are reported where both ova grew and developed at the end of term and both children were born alive, one by operation and the other in the natural way. The prognosis is grave for both the mother and the child. The treatment is plainly indicated by the course and duration of each case. If rupture occurs, prompt celiotomy is necessary. He analyzes 88 cases found in the literature and gives a tabulated statement of the same.

93. **Vaginal Hysterectomy in Uterine Cancer.**—The object of Janvrin's paper is to put himself on record as a decided advocate of vaginal hysterectomy in cancer of the uterus in its early stages, including also some cases of adenoma and carcinoma of the uterine body and to express his conviction that we can cure a good percentage of cases so complicated. Further, he places himself on record as an advocate of either vaginal or abdomino-vaginal hysterectomy in many other still more advanced cases where operation can generally prolong life and make it more endurable.

94. **Retrodisplacement.**—Baldy offers the following method as an improvement on Webster's operation, which is in many respects more satisfactory than any heretofore offered. "The round ligament on each side of the uterus is picked up and a ligature thrown about it close to the uterus, so placed as to secure the artery. The round ligaments are then severed close to the ligatures. This leaves the uterine ends of the ligaments ligated and the other ends free and bleeding. The bleeding is controlled by a fine ligature to each vessel or by the sutures which fasten them in the next step of the operation. A pair of forceps is now made to perforate the broad ligament from its posterior aspect (at the point at which the round ligament is cut on the anterior surface), and the cut end (the pelvic end) of the round ligament is grasped in the bite of the forceps and pulled through the hole in the broad ligament (made by forceps in perforating) until it protrudes on the posterior side of the broad ligament. The opposite side is treated in a similar manner. The cut ends of the round ligaments are now attached by means of sutures on the cornua of the uterus on

the posterior aspect of the uterus directly back of the original point of attachment of the normally attached round ligament. The point of attachment may be higher or lower than this, as the surgeon may find necessary to accomplish the result. If necessary as much of the round ligament is cut off, before suturing it to the uterus, as is necessary to take up any slack and give the proper amount of tension and support to the uterus. This ends the operation. The suture is a continuous one and may be either chromicized gut or silk. The effect of this procedure is to draw the fundus of the uterus upward and forward into a perfect position. The uterus remains a pelvic organ. It has no artificial supports. It is as free to expand in pregnancy as it was originally, with no greater danger of the tearing away of its supports. There are no adhesions to give future trouble from pain or possible strangulation of the bowels." He says there is absolutely no tension after this operation and, therefore, no danger of pregnancy or anything else destroying the operation or of an abortion occurring.

106. **The Feeding of Children.**—The dangers in the dietetic management of children during the second year are under-feeding and over-feeding. Too abundant and unsuitable food may produce the same effect as under-feeding. We should, therefore, try to supply the proper material. Weaning should be done, if possible, in the cooler months, but if it is necessary to have it done in the warm period it should be gradual. Southworth mentions the use of gruels and advises against the abandonment of the nursing bottle too early as it is available for feeding at all times, which is often of advantage, and insists on the importance of milk as an article of diet through the second year. He suggests the following arrangement of the bill of fare: 7:30 a. m., breakfast, including bottle of milk (diluted if necessary); 11 a. m., bottle of milk, with crust or zweibach; 2 p. m., dinner, with rather less milk as the other food is increased; 6 p. m., supper, including bottle of milk; 10 p. m., bottle of milk. Eggs, soft-boiled, may be given early near the beginning of the year, and dry white bread may be allowed if the teeth are good. The use of the teeth on a hard crust is doubtless beneficial as favoring salivary secretion. Fruit juices are also to be allowed. Thoroughly soft baked apple, entirely freed from the skin and hard portions of the core, is permissible, and in the middle of the year vegetables may be tried, such as spinach, carefully passed through a sieve; afterward fresh green peas, asparagus tips or tender string beans when obtainable, which may be treated in the same way. Toward the end of the year stewed celery and tender boiled onions may be added. Potato when given should be baked and mealy and well broken up with the fork. Meat in its usual form must await the development of the masticatory powers, but beef juice expressed from lightly-cooked steak may be given even before the twelfth month. The finely minced white meat of poultry may also be given about the middle of the second year, scraped rare pulp of steak, roast beef, roast mutton or mutton chop, the tough fiber being carefully avoided, can be given as early as the second year. An excess of meat and its derivatives should be avoided, and the amount should bear some relation to the amount of exercise and out-of-door life. He speaks strongly against taking children to the table too early, as they see things they want and are likely to get them, to their disadvantage. Desserts are better left alone by children; they consume too much of their attention, and sweets are inadvisable.

120. **Appendicitis.**—From a general review of the subject of appendicitis and its frequency Cooper concludes that it is apparently much more common in America than in Great Britain. He speaks favorably of Ochsner's method of treatment as having undoubted efficacy in certain cases and lays stress on the following facts: Many persons have a chronic pathologic condition of the appendix from whom no history of an acute attack, either initiatory or during the course of the chronic trouble, can be obtained. A big percentage of patients present the phenomena of finger-tip-pressure tenderness over McBurney's point, consequently finger-tip-pressure tenderness is no true index of the onset of a new appendiceal trouble. This

must be a recognized condition, unless its previous absence be known, in an attempt to diagnose doubtful abdominal conditions. Such patients do not present localized rigidity, even in those cases in which the diseased appendix can be rolled under the finger. He calls attention to the efficacy of local treatment during the convalescent stage of acute appendicitis helping to clear up inflammatory products around the appendix as in other regions of the body.

**130. Iron.**—The action of iron is fairly thoroughly treated by Aulde. It is absorbed very slowly by the stomach. The greater portion is probably excreted by the bowel with the production of more or less headache due to the direct action of the iron on the cerebral center or reflexly from the effect on the intestinal tract. Introduced directly into the circulation, non-coagulating salts of iron cause paralysis of the central nervous system and of the vasomotor nerves, loss of voluntary motion, enormous fall of blood pressure and death. Its toxic action may be avoided by the administration of small doses, making its action a gentle stimulant instead of a toxic irritant. The author specially notes the action of the combination of iron with zinc and enumerates the principal clinical application of iron as follows: "As a hematinic, iron must be recognized as a superior remedy and with suitable collateral or alternate medication much will be accomplished by its employment, provided that it be given in small doses so that the degree of irritation shall not exceed that of gentle stimulation. It may be used in nearly all cases where impaired nutrition is the dominant factor. The addition of nuclein from animal sources is recommended in acute as well as chronic cases of blood dyscrasia as a means of restoring and maintaining a normally antiseptic condition of the body fluids, thus favoring cell activity. This is especially to be commended in the case of catarrh affecting the mucous surfaces, since it serves to complement nature's efforts in restoring the vitality of the cellular structures, by sending an improved secretion (excretion?) to fortify and augment cell resistance. Stress is laid upon the value of the arseniate in these conditions, because of the influence of the arsenic content upon systemic metabolism. Particular attention is directed to the exceptional value of iron and zinc in combination as a protoplasmic stimulant, noting the absence of action upon the sexual function, a deficiency which may be supplied by the alternate exhibition of chlorid of gold and sodium in combination with nucleinic acid from animal sources."

**135. The Bottini Operation.**—Walker's article discusses the operation and reports cases, and he seems to think it has a decided future. He points out the alleged objections, and enumerates the following advantages: 1. It offers a greater number of cures and a less number of fatal cases than any other procedure. 2. It can be done without the use of a general anesthetic. 3. It is never attended with shock. 4. It does not require a patient to be confined to bed for a long time. 5. Its effects are in many cases immediate. 6. The accidents and complications are certainly not so serious as in other operative measures. 7. It can be done in a class of cases where the severer operative measures are contraindicated.

**139. Sources of Error in Hearing Tests.**—The possible sources of error in functional tests of hearing which must necessarily be largely suggestive and require the co-operation and correct response on the part of the patient are treated by Andrews. Some of the more frequent errors are mentioned and means of avoidance suggested. They may arise from faulty constructed or poorly-adapted instruments, failure on the part of the examiner to understand his instruments or to use them properly or from failure on the part of the patient to promptly and accurately respond to the various tests. The Galton whistle and the tuning fork stand alone as instruments for making functional examinations. There is a great variety of tuning forks on the market, most of them more or less defective. The weighted forks have an advantage of being free from overtones, but are useless for testing bone conduction because of the jar transmitted through the handle, the sensation of which the patient is liable to mistake for sound. The presence of overtones is the great objection to unweighted tuning

forks, the patient sometimes answering when he only hears the overtones. A good test for overtones in a fork is to strike about the middle of the prong with some light, hard object as a pencil. The metallic ring is the overtone, and is one or more octaves above the true tone of the fork. Another objection to many of the forks is the length of time in which they continue to vibrate and a fork should be selected which the normal ear can hear only from 25 to 40 seconds. In making repeated tests in the ear in order to secure accuracy, much available time is lost while waiting for the fork to run down and the patient's attention wears out, and his replies are uncertain. It is necessary to determine how long the normal ear can hear the fork used. The amount of impairment in any given ear may be expressed by a fraction the denominator of which represents the time a normal ear hears the fork, while the numerator shows the time the impaired ear hears it. Many published records or tests are valueless because of the neglect to specify the time in which the normal ear could hear the fork. There is also a wide variation in the relative time which different forks of the same pitch can be heard by bone conduction and by air conduction in the same way. The shape of the fork, size of the handle and the temper of the steel each have an influence. We should have a standard for each individual fork not only for air conduction but bone conduction as well. In testing bone conduction, it makes a decided difference upon what part of the mastoid the handle of the fork is placed and also whether it is allowed to touch the back of the auricle. Probably the best position for the handle of the fork is directly over the mastoid antrum. The amount of pressure exerted on the handle of the fork also makes a difference. In air conduction it is a good plan to cover the patient's eyes and compel him to depend entirely upon his ears as they imagine they hear the sound if they see the fork still vibrating. Whenever there is a suspicion of accuracy the fork should be held in the hand so that the finger can be passed down along the prong of the fork, and thus gradually stop the vibrations. Sometimes the patient thinks he hears it after it has ceased to vibrate. Sometimes tinnitus so closely resembles the sound of the fork that the patient is unable to tell when he has ceased to hear the vibrations and a fork of a higher pitch should be substituted. Repeated tests should be made for the sake of accuracy. In using the high forks the patient will sometimes state that he hears when he only feels the vibrations of air set in motion by the movements of the fork. Holding the open end of the fork toward the ear will obviate this. It is necessary to keep the hair away from the ear, for if the vibrating fork comes in contact with a stray hair or two a sensation will be produced which the patient may mistake for a sound. The temperature of the instrument should also be regarded. It may be necessary to warm it to prevent any undue sensation. In the lower forks the vibration transmitted to the handle is much greater in proportion to the volume of the sound than in the higher forks. In testing bone conduction for the lower tones it would be difficult to determine whether the patient hears the fork or merely feels the jar. Andrews is not aware of any plan that will secure the desirable accurate measurement of bone conduction in the lower tones.

**143.**—This article appeared in *THE JOURNAL* of January 18, p. 155.

**146. Gonorrhea.**—Gonorrhea in the female is discussed by Byron Robinson, with details which are too elaborate to be fully reproduced. He says the treatment of gonorrhea in the female is unsatisfactory because when the microbes gain the genital mucosa they at once appropriate it as home. It wounds the mucosa and serosa, making atria for infection. It desquamates epithelia and endothelia. These atria are entered by all existing pathogenic microbes producing inflammation, which proliferates connective tissue, whose fate is cicatrices and contraction (stricture). Cicatricial contraction (the destructive results of gonorrhea) distorts the mechanism of the tractus genitalis and adjacent structures, compromising structure, function, circulation (blood and lymph), traumatizing nerve periphery, lessening nourishment and resistance. The

gonococcus, under quiet life on the mucosa, gradually becomes less virulent with cultures until it loses its virulence or the individual resistance conquers it, and that that remains is results, cicatrices. However, at the great functions of the genitals, menstruation, abortion, labor secretion (and excessive coitus and alcohol) the gonococcus partially revives its virulence from new food (due to hyperemia and consequent excessive secretion). Thus the gonococcus in the female tractus genitalis (and peritonium) is liable to live continuous during the sexual or menstrual life from recurrent food supply producing new gonococcus cultures.

148. **Gastrojejunostomy.**—Cordier reports a case of gastrojejunostomy performed six years before, the patient finally dying of acute pneumonia and the postmortem being obtained. The Murphy button used in the gastrojejunostomy was never passed during life, but after death it was found still in the stomach and the anatomic condition of the stomach and bowel, notwithstanding that the pylorus was practically closed, was perfectly satisfactory. The presence of the button in the stomach had never given rise to a single symptom during the nearly seven years that it had remained there. He thinks this fact is in favor of its employment, considering also that it greatly shortens the time of operation.

151. **Tuberculosis.**—Dickey deprecates the exaggeration as to the contagiousness of consumption, which he thinks has been much overdone, and if such ideas were followed out they would lead to serious hardship and unnecessary legislation, which would be recognized at once as unreasonable. Tuberculosis, he says, is not a contagious disease. The contact of an individual suffering from it is practically free from danger. The tubercle bacilli being found in the sputum, as well as other secretions of the body—not in the breath—very rarely in the skin, makes it a communicable disease. If due care is taken to destroy the tuberculous expectoration and secretions as well as articles of food in which the bacilli are found, the danger of contracting the disease is practically nil. He points out that the building of sanatoria reduces the death rate from consumption in their immediate vicinity as shown by German experience. He does object to consumptives marrying, as he believes heredity an important factor in the causation of the disease.

162. **Sympathetic Ophthalmia.**—From the review of a number of cases, De Schweinitz and Shumway conclude that the best that can be said at the present time is that an eye, so wounded that a plastic iridocyclitis or uveitis appears, sometimes sets up in the opposite eye an analogous inflammation, to which we give the name sympathetic ophthalmitis, and that in all probability this depends upon an infection of the so-called sympathizing eye by some form of toxin which they liberate, but that sometimes exactly analogous lesions will produce only an irritation which promptly disappears on removal of the originally injured eye and disappears, moreover, without leaving a trace of organic change. It would further seem that some undiscovered, perhaps constitutional, perhaps local, condition determines on the one hand the inflammation and on the other hand the temporary so-called irritation.

163. **Blood Diagnosis.**—White knows of no disease that can be absolutely diagnosed by means of formed blood elements. Even in malaria the parasite has to be found. The only apparent exception is presented by leukemia. Splenomyelogenous leukemia, with a high percentage of leucocytes and a marked degeneration of erythrocytes are hardly to be mistaken, but lymphatic leukemia is not so certain and may closely resemble sarcoma and other diseases. That the examination of the blood is a valuable and essential part of the thorough examination of the patient does not need argument. The blood analysis should be a thorough one, but this is too often overlooked, and he calls attention to the necessity of studying the formed elements of the blood from their morphologic standpoint as well as from their count, and uses certain diseases to illustrate this fact. The complete analysis of the blood should be considered only with the results of clinical evidence, the duration of the disease and, if possible, the presence of complications. He remarks in conclusion that certain typical conditions almost invariably

produce changes in the blood. These changes may be of a positive or of a negative value in the diagnosis of the disease. In some conditions the blood changes may absolutely clinch the evidence pointing to the diagnosis; in other cases, with our present knowledge, the blood offers absolutely nothing as an aid in the diagnosis. This, however, can be said of any branch of medical or surgical methods of examination of which blood examinations are only a part. In any case blood analyses, to be of any value, must be considered only in connection with the findings of other methods of examination, the history of the illness, and in the presence of complications.

## FOREIGN.

Titles marked with an asterisk (\*) are abstracted below.

The Lancet (London), May 10.

- 1 The Seed and the Soil. W. Howship Dickinson.
- 2 \*Embalmng the Dead. J. G. Garson.
- 3 \*The Quiescent or Latent Period in the Course of Grave Abdominal Inflammation. A. H. Tubby.
- 4 Some of the Surgical Aspects of Glycosuria and Diabetes. (To be concluded.) Llewellyn C. P. Phillips.
- 5 Case of Poisoning by Morphia Injection Treated by Infusion of Salt Solution. Edward F. Willoughby.
- 6 \*An Interesting Phenomenon Occurring in Tachycardia. Herbert D. Everington.

British Medical Journal (London), May 10.

- 7 \*Surgical Treatment of Arteriovenous Aneurism. Frederick Treves.
- 8 \*Splenic Leukemia and Phthisis Combined in the Same Patient. G. Parker.
- 9 The Blood in Cases Affected with Filariasis and Bilharzia. Hematobia. Alfred C. Coles.
- 10 Case of "Infective Endocarditis" Treated with Antistreptococcus Serum. H. M. Cooper and Cyril Ogle.
- 11 Case of Fatal Anemia Presenting Some Unusual Blood Changes. O. K. Williamson and E. W. Martin.
- 12 Spontaneous Gangrene of Both Lower Limbs in a Man Aged 36. William Mitchell.
- 13 On Treatment of Hemophilia with Calcium Chlorid. C. Edward Wallis.
- 14 Notes on Cases Illustrating the Use of Adrenalin Chlorid in Ophthalmic Nasal and Aural Surgery. A. Stanley Green.

Intercolonial Medical Journal of Australasia (Melbourne), March.

- 15 On the Significance of the Term "Cure" in Medicine. James Jamieson.
- 16 \*The Etiology of Typhoid Fever. Thomas Cherry.
- 17 Prostatectomy. George A. Syme.
- 18 Intussusception in Infants. R. Hamilton Russell.

Bulletin de l'Acad. de Med. (Paris), April 29.

- 19 \*Rats and the Plague. N. Gamaleia (Odessa).—Sur les rats et la peste.
- 20 New Model of Stethoscope. Troussaint (Marseilles).—Le diaphoscope.
- 21 Treatment of Malarial Fever with Arrhenal. A. Gautier.—Sur le traitement arrhénique des fièvres palustres.

Bulletin Soc. Med. des Hop. de Paris, March 27 to May 8.

- 22 (No. 11.) Independence of Spermatogenesis and Internal Secretion of Genital Glands. Variet.—Ind. de la spermatogenèse et de la sécrétion interne des glandes génitales.
- 23 Acute Anterior Spinal Paralysis. P. Londe.—Polyévrte avec paralysie faciale.
- 24 Alopecia from Eruption of Wisdom Tooth. L. Jacquet.—L'elade symétrique par éruption précoce de la dent de sagesse.
- 25 (Case Reports.) Cas d'hermaphroditisme. A. Petit.—Goutte aigue du pharynx. Lermoyez.—Ascite lactescente et cirrhose atrophique. Souques.—Ibid. C. Achard.
- 26 (No. 12.) Organic Mercurial Compounds. H. Danlos.—Sur quelques combinaisons organiques de mercure.
- 27 Enlargement of Heart. Dissociation of Digitalis and Couple Rhythm. P. Merklen.—Grande dilatation du coeur. Action dissociée de la digitale et rythme couplé.
- 28 (Case Reports.) Compression of the moelle dorsale par un endothéliome. E. Hirtz.—Fièvre typhoïde à symptômes spinaux. H. Grenet.—Erythème scarlatiniforme intermittent d'origine paludéenne.
- 29 (No. 14.) Spasmodic Form of Syringomyelia. G. Guillaum.—La forme spasme de la syringomyélie.
- 30 Polycystic Kidney in Adult. P. Menetrier.—Gros rein polycystique chez l'adulte.
- 31 Free Foreign Bodies in Pericardium. Duflocq.—Fibroïdes libres dans le péricarde.
- 32 \*Saline Injections and Retention of Chlorids in Certain Morbid States. Ch. Achard.—Injections salines et rétention des chlorures dans certains états morbides.
- 33 (Case Reports.) Ascite lactescente. Cancer du colon et cancer sec. du foie atteint de cirrhose alcoolique hypertrophique. C. Achard.—Goutte aigue du pharynx. H. Verdale.—Hystérie à début sénile. A. Souques.—Paralysie chez un garçon causée par l'usage d'une trompette à embouchure de plomb. G. Variot.—Hémiplégie protubérantielle. Touche.
- 34 (No. 15.) \*Cystic Affection. G. H. Lemoine.—Maladie kystique.
- 35 \*Biliary Melanoderma. A. Gilbert.—Les mélanodermies d'origine biliaire.

- 27 \*Ibid. H. Vincent.  
 38 Trivalve Speculum. A. Siredey.  
 39 \*Sore Throat in Scarlet Fever. G. Variot.—Nouv. recherches clin. sur le processus angineux dans la scarlatine et sur ses irradiations.  
 40 \*Sulphauria and Sulphated Saline Injections. C. Achard.—Sulfaurie et injections salines sulfatées.  
 41 Chloruria in Nephritis. H. Claude.—La chlorurie alimentaire expérimentale dans les néphrites.  
 42 (Case R. ports.) Anévrisme de la portion ascendante de l'aorte. Dudoq.—Cas de mort subite dans l'appendicite. Lion.—Goutte aigue du pharynx. G. Scherb.  
 Revue d'Orthopedie (Paris), xiii, 1 and 2.  
 43 \*Bloodless Treatment of Congenital Luxation of the Hip-Joint. C. Guillini.—Le traitement non sanglant de la lux. congén. de la hanche par rapport aux difformités du fémur.  
 44 Apparatus for Continuous Traction and for Reduction of Fractures. M. Menard.—Essais de reduction de fractures sur le cadavre à l'aide d'un appareil à traction continue et des rayons de Roentgen.  
 45 \*Points in Treatment of Ectopia of the Testicles. P. Coudray.—Traitement de l'ectopie testiculaire.  
 46 Dorsal Luxation of the Thumb. P. Grisel.—La luxation dorsale externe de l'articulation métacarpo-phalangienne du pouce.  
 47 (No. 2.) Osteotomy in Genu Valgum. P. E. Launois.—Genu valgum double invétéré. Redressement par ostéotomie.  
 48 \*"Growing" Coxa Vara. Froehlich (Nancy).—Anatomie path. et traitement de la coxa vara essentielle de croissance.  
 49 Precarpal Amputation. H. Morestin.—Amputation précarpienne.  
 50 Genu Recurvatum in Coxalgia. Phocas (Lille).  
 51 Incomplete Backward Luxation of the Foot. H. Judet.—Luxation incomplète du pied en arrière.  
 52 Tardy Rachitic Dwarf Growth. Patel (Lyons).—Cas de nanisme rachitique à forme tardive.  
 Naunyn's Archiv f. Exp. Path., etc., (Leipzig), xlvii, 3 and 4.  
 53 Transformations of Quinin. A. Merkel.—Stoffwechselprodukte des Chinins.  
 54 Experimental Feeding with Chondroitin-Sulphate. A. Kettner.—Ueber Fütterungsversuche mit Chondroitin-Schwefelsäure.  
 55 Die Thätigkeit des überlebenden Säugethierherzens bei Durchströmung mit Gasen. R. Magnus.  
 56 Ueber Athemversuche mit einigen Giften. Hayashi (Tokio).  
 57 Absorption of Carbohydrates from Rectal Mucosa. F. Reach.—Ueber Resorption von Kohlehydraten von der Schleimhaut des Rectums.  
 58 Einige Beobachtungen an Venenpuls. D. Gerhardt.  
 59 Influence of Alcohol on Metabolism of Albumin During Fever. A. Ott (Oderberg).—Ueber den Einfluss des Alkohols auf den Eiweißstoffwechsel bei Fiebernden.  
 60 Ueber Bufonin und Bufotalin, die wirksamsten Bestandtheile des Krötenhautdrüsensecretes. E. S. Faust (Strassburg).—Ausgeführt mit Unterstützung des Elizabeth Thompson Science Fund in Boston.  
 Archiv f. Gynaekologie (Berlin), lxvi, 1.  
 61 Die Variationen im Bau des Mesometrium und deren Einfluss auf die Entstehung von Menorrhagien und von Fluor. A. Theilhaber.  
 62 Zur Aetiologie der Placentarysten. W. Vassmer (Hannover).  
 63 Early Interruption of Tubal Pregnancy. T. Dobbert (St. Petersburg).—60 Fälle in frühen Entwicklungsstadien unterbrochener Tubenschwangerschaften.  
 64 Die vaginale Anwendung der Braun'schen Blase in der Geburtshilfe. Voigt (Dresden).  
 65 \*Ueber scheinbar primäre in Wirklichkeit metastatische Krebskrankung der inneren Geschlechtsorgane bei Tumorbildung in Abdominalorganen. C. Römer (Breslau).  
 66 Metritis Hysterica. Vedeler (Christiania).  
 67 Eine besondere Art seltener hämorrhagischer, leukocyitärer Hyperplasie der Gebärmutter Schleimhaut. S. Gottschalk (Berlin).  
 68 Bossi's Dilator. G. Leopold (Berlin).—Ueber die schnelle Erweiterung des Muttermundes mittelst des Dilatoriums von Bossi.  
 Archiv f. Klin. Chirurgie (Berlin), lxvi, 1.  
 69 \*Improved Technik for Operating on Cancer of the Rectum. M. Jaffe (Posen).—Indicationen und Prognose der Operationen des Mastdarmkrebses, mit einem Beitrag zur Modification der Operationsmethoden.  
 70 Deformities of the Large Intestine. A. Frommer (Cracow).—Zur Casuistik der Anomalien des Dickdarmes.  
 71 \*Sympathectomy in Exophthalmic Goiter. Balaceanu (Bucharest).—Die totale und bilaterale Resektion des Sympathicus cervicalis beim Morbus Basedowii.  
 72 Trephining in Cortical Epilepsy. W. J. Rasmowsky (Kasan).—Zur Frage der Trepanation bei corticaler Epilepsie.  
 73 \*Extensive Resection of Intestines. E. Payr (Graz).—Ueber ausgedehnte Darmresektionen. Bemerkungen ueber chemische Peritonitis und das Stauungstransudat bei Strangulationsileus.  
 74 Giant Celled Sarcoma and Plasma Cells. G. Friedlaender.—Sarcome, Riesenzellsarcome und Plasmazellen.  
 75 Bacterium Coli as a Pyogenic Coccus. L. de Gaetano (Naples).—Kokkenformulens B. C. mit pyogener Wirkung im Menschen und Versuchsthiere.  
 76 Staphylococcus as Cause of Benign Bone Neoformations. A. A. Bobroff (Moscow).—Staph. als Ursache benigner Knochenneubildungen.  
 Berliner Klin. Wochenschrift, April 17. Von Leyden Number.  
 77 The Clinical Importance of the Personal Factor in Disease. Sir Dyce Duckworth (London).  
 78 Diabetogenic Leucemalms. R. Lepine (Lyons).—Sur l'existence de leucemalms diabetogènes.  
 79 Colicardence of Articular Rheumatism with Typhoid Fever. P. K. Pel.—Ueber die Coincidenz von Polyarthritits rheumatica acuta mit Abdominaltyphus.  
 80 Cutaneous Tubercular Affections and Their Relations to Internal Organs. O. v. Petersen (St. Petersburg).—Die tuberkulösen Erkrankungen der Haut und ihre Beziehungen zu den inneren Organen.  
 81 \*Dissociated Venous Pulse. G. Ascoli (Genoa).—Ueber ueberzahlige Venenpuls. Zur Klinik der Dissociation der Herzfunction.  
 82 Case Simulating Banti's Disease. E. Hocke (Prague).—Ueber ein an den Banti'schen Symptomencomplex erinnerndes Krankheitsbild wahrscheinlich hervorgerufen durch cong. Lues.  
 83 Experimental Study of Inhalation of Oxygen. J. Kovas (Budapest).—Exp. Beitrage ueber die Wirkung von Sauerstoffinhalationen.  
 84 Stroke Auscultation and Resonance, Especially for Determination of the Outlines of the Ventracles. A. Blad (Copenhagen).—Ueber Streichauscultation und Transsomanz, besonders die Bestimmung der Ventrikelgrenzen.  
 April 28.  
 85 \*Anesthesin as a Local Anesthetic. C. v. Noorden (Frankfurt a. M.).—Ueber para-Amidobenzoesäure-Ester als locales Anästhetikum.  
 86 Polyneuritis Consecutive to Malaria. A. M. Luzatto (Berlin).—Fall von Polyneuritis nach Malaria, mit Autopsie.  
 87 Zur Therapie der Pharyngitis granulosa und der Pharyngitis lateralis. M. Halle (Berlin).  
 88 \*New Technik for Testing the Gastric Functions. Sahli (Berne).—Ueber ein neues Verfahren zur Untersuchung der Magenfunctionen. (Concluded from preceding number.)  
 Deutsche Med. Wochenschrift (Leipzig), May 1.  
 89 Lead Poisoning. A. Seeligmueller (Halle).—Zur Pathologie der chron. Bleiintoxikation.  
 90 \*Implantation of Tendon into Bone. J. Wolff.—Ueber ostale Sehnenplastik.  
 91 \*To See the Outline of the Stomach Without Artificial Aid. M. I. Knapp (New York).—Wie man die Magencontour ohne Hilfsmittel sehen kann.  
 92 Value of Iodiform in Inguinal Lesions. G. J. Mueller.—Zur Behandlung des venerischen Geschwürs und der Lymphadenitis inguinalis.  
 93 Fall von extragenitaler Syphilisinfektion. Schnabel (Magdeburg).  
 Muenchener Med. Wochenschrift, April 22.  
 94 Endovenous Injections of Sublimate. A. Serafini (Padua).—Ueber die endovenösen Injektionen von Aetzsublimat.  
 95 Explanation of Action of Iodin in Arteriosclerosis. Jodlbauer.—Kann man eine Iodwirkung bei Arteriosklerose pharmakologisch begründen?  
 96 Incarceration of Uterus in Ring Pessary. G. Wiener.—Fall von Uteruseinklemmung in ein Pessar.  
 97 Drumstick Fingers with Atrophy of Terminal Phalanges. W. Stoeltzing (Hersfeld).—Trommelschlegelfinger mit Atrophie der Endphalangen.  
 98 Affections of the Pancreas and Diabetes. Teschemacher (Neuenahr).—Pankreaserkrankung und Diabetes.  
 99 Diagnostic Importance of Angiomata of the Skin. Rosenbaum.—Ueber die diagn. Bedeutung der Angiome der Haut.  
 100 Return Radial Pulse. A. Meyer (Berlin).—Rückkläufiger Radialpuls.  
 101 \*Importance of Quinin in the Treatment of Wounds. H. Marx (Lubeck).—Die Bedeutung des Chinins für die Wundbehandlung.  
 102 Hitherto Undescribed Localization of Lead Poisoning. G. Koster (Leipzig).—Eine bisher noch nicht beschriebene Lokalisation der Bleilähmung. (Concluded from preceding number.)  
 April 29.  
 103 Recurring Herpes of Male Urethra. Bettmann (Heldelberg).—Ueber recidivirenden Herpes der männlichen Harnröhre.  
 104 Escape of Hemoglobin from Corpuscles Treated with Sublimate. M. Matthes (Jena).—Ueber den Austritt des Hemoglobins aus sublimatzehärteten Blutkörperchen.  
 105 Importance of Slight Variations in Atmospheric Pressure for the Human Organism. O. Rosenbach (Berlin).—Die Bedeutung kleinerer Schwankungen des atmos. Druckes für den menschlichen Organismus.  
 106 Dormiol in Epilepsy. J. Hoppe (Uchtspring).—Beitrag zur Behandlung des Status Epilepticus.

**2. Embalming the Dead.**—In this article, which is not directly medical but still of interest, Garson remarks that the ancient Egyptians knew how to successfully preserve bodies, but their methods were tedious and much more complicated than modern methods. He believes that embalming is not a matter which should be left to the undertaker alone, and it should be done about twenty-four hours after death. He thinks the best preservative of blood vessels to be one of bichlorid of mercury or some similar acting salt and methylated spirit; the solution may also be used for external application and for injection in the cavities and hollow viscera. Two gr. to each ounce of injection fluid are usually best to begin with, but the strength should be somewhat increased even to double strength during the latter stages of the process. To avoid too much drying of tissues some glycerin may be added, not exceeding one-quarter of the bulk of the spirits used, usually less. Two gallons or nine liters are sufficient for the male adult and five liters for the female. To get the best results the injection should be done slowly to avoid rupturing the vessel and there should be a gauge to indicate the force with which it is entering the body, whether this is applied by pump or by fountain syringe. Further details are mentioned. In a case where the bursting of an artery in the thorax or abdominal cavity has occurred, the injection should be performed upon the ruptured vessel which must be exposed. In case of general anasarca, the dropsical condition so far as possible should be gotten rid of and the best plan is to siphon out the fluid in the abdominal cavity with an India-rubber tube, then elevating the limbs and tightly bandaging from the distal extremities upwards and press out the fluid before injection. He gives the order of working in case a postmortem is required before embalming and in case that has to be done first. If the embalming can be done first the postmortem should be delayed at least twenty-four hours after its performance.

**3. The Quiescent or Latent Period in Abdominal Inflammation.**—Tubby's paper calls attention to the quiescent or latent period which is sometimes a prominent feature in intestinal injuries, injury or bruising of the peritoneal connections of the viscera, with interference with their blood supply, acute disease of the genital organs, especially the Fallopian tubes, and acute appendicitis. He says especially in appendicitis it is a well-marked symptom. In nearly all acute stages, according to Symonds, a stage is reached soon after the onset marked by a session of all acute symptoms and the neglect of this may lead to disease. The most important information is obtained from a careful study of the pulse and temperature. The most serious cases frequently have an accelerated pulse with subnormal temperature, and, if this occurs with the history or the onset of the attack, it justifies immediate operation. If in a case of appendicitis an initial rise of temperature and pulse are followed by a fall in both, succeeded after a few days by a rise, it means the presence of a considerable amount of pus and the abscess should be evacuated. A transient or persistent rigidity and absence of all other symptoms are important, especially when signs of intestinal peristalsis are absent, as indicating a serious condition. Distension may be absent, but if it persists for longer than twenty-four or thirty-six hours and is unrelieved by treatment such as turpentine enemata it is of serious significance. If vomiting recurs after the quiescent period in spite of careful feeding and nursing, especially after the administration of sedatives, we must not underestimate the symptom. The leucocyte count also is of importance during the quiescent period. He thinks this method of clinical examination is likely to be one of great importance.

**6. Tachycardia.**—In the case reported by Everington the patient was taken with violent action of the heart in the course of apparently acute rheumatism and though there was no evidence of organic disease, the heart beats came up to 220 per minute at one time. The patient was directed to take deep breaths, and after several of these inspirations it was found that the heart beat had fallen to 124 or nearly 100 beats per minute. The fact that the mere mechanical taking of deep inspirations was sufficient to reduce the heart beat has been noticed before by Sir William Broadbent and by Rosenfeld and Allbutt, but he thinks the observation is of sufficient interest to be recorded.

**7. Arteriovenous Aneurism.**—Treves reports four cases occurring in the African war, two of varicose aneurism, and two of aneurismal varix. He remarks that the only operative measure to be commended in these cases is ligation of the vessels at the wounded site and the ideal operation would be to ligature both arteries and veins above and below the abnormality. This is not always practicable, and in one of these cases of aneurismal varix of the left groin he simply ligatured the common femoral above the lesion and the superficial femoral below, nevertheless with excellent results. He remarks that these show what satisfactory results may follow operative measures themselves far short of perfection.

**8. Splenic Leukemia in Phthisis.**—Parker reports the first case of this condition observed in Great Britain, and discusses the diagnosis. He thinks perhaps an injury received may have had some influence.

**16. Typhoid.**—In Cherry's opinion many mild cases of fever called febricula are really cases of typhoid, and may serve to distribute the contagion. Typhoid fever itself, he thinks, may be a composite disease or a series of diseases, caused by closely allied organisms. He does not think it necessary to assume a *de novo* origin, though it can not be disproven.

**19. Rats and the Plague.**—A communication received from Gamaleia based on the examination of 23,131 rats, announces that the sewer rat is seldom found on ships. Out of nearly 10,000 rats found in the center of Odessa about 95 per cent. were the sewer rat—*mus decumanus*—while 96 per cent. of 1178 rats found on vessels were of the species *mus rattus*, or the domestic rat. He also found that the three principal varieties

of the latter, the black, the red and the Alexandrine rat, do not live together but inhabit different vessels. The black rats were found mostly on ships from England and the Black Sea ports, while the Alexandrines were found on Turkish and Egyptian vessels and the red species on ships from the Orient. He found that the plague among the town, or sewer rats, was strictly localized in three foci. One was the restaurant where the first patients with the plague were discovered. This focus was exterminated by the destruction of the supplies of rice, cabbages, etc., in the cellar. The second focus was a freight platform, and this focus also was exterminated after the destruction of a few bags of spoiled rice on it. The third focus is a large freight warehouse; as so many goods are stored there, it has proved impossible to destroy them all; consequently this focus still exists. The determination of these limited foci suggests that possibly the plague is not transmitted directly from one sewer rat to the other, but indirectly by the mediation of infected rice or other foodstuff. Proust commented on this communication that possibly the immunity enjoyed by Europe in respect to the plague may be due to the predominance of the sewer rat, which seems to be less susceptible to the natural plague than the other species.

**32. Saline Injections and Retention of Chlorids in Certain Morbid States.**—Achard tabulates a number of cases of various diseases in which he had injected a liter of saline solution. The results showed that the injections failed to induce diuresis. He had a similar experience with salt ingested by the mouth. He attributes the absence of diuresis to the varying retention of sodium chlorid by the tissues in different morbid states. It is retained in the dissolved form, and consequently a large amount of water is retained with it. The diuresis was not increased except in one case in which the patient had shown evidences of previous polyuria. He thinks that the general tendency is to resort too much to these injections, and that they are useless as diuretics in diseases accompanied by a retention of the chlorids. He has demonstrated that pneumonia takes the lead in this respect, but is closely followed by the majority of acute infectious diseases, attacks of asystolia, uremia, infectious icterus, etc.

**34. Cystic Affection.**—Lemoine considers polycystic degeneration of organs as the evidences of an essential affection of glandular organs, characterized by the dilatation of the acini or excreting canals under the normal pressure of the fluids which they contain. It is thus an actual glandular angioma. The tendency is probably congenital.

**35. Melanoderma of Biliary Origin.**—Gilbert attributes to the presence of bile pigments in the blood the nevi, tiny moles, freckles, dark circles around the eyes, the so-called bilious complexion and the pigmentations of pregnancy. The tendency to melanoderma may remain latent until some casual cause may incite it to activity, some mechanical or chemical factor, exposure to the sunlight, the irritation of a blister, or a medicine. These various causes do not induce the pigmentation except in those predisposed by a tendency to cholemia, and it is frequently a revealing sign of the latter.

**36 and 37. Contagion of Vincent's Angina.**—Three undeniable cases of contagion of the angina or stomatitis caused by the association of the spirilla and the fusiform bacillus are reported. Vincent reiterates that the promptest method of cure is to rub the parts thoroughly with a tampon impregnated with tincture of iodine, removing all the false membranes.

**39. Study of Sore Throat in Scarlet Fever.**—Variot's experiences include 864 cases of scarlet fever in children under 14. He states that the angina is polymorphous, with or without exudation, and that the diphtheria bacillus can be found in it from the start in a certain proportion of cases. In others the angina may present all the characteristics of the diphtheritic sore throat but without the diphtheria bacilli. Superficial ulcerations are frequent and the influence of the throat process and its irradiations determines the gravity of the disease and the temperature curve. True nephritis was observed in only about 1 per cent. of all his cases of scarlet fever, but slight, transient albuminuria was noted in 101. He makes a practice

of keeping the children in bed and on a strict milk diet for five weeks, and attributes to these precautions the small proportion of cases of nephritis. ("Tous nos petits malades sont soumis au régime du lait exclusif pendant cinq semaines. De plus il leur est bien difficile de se refroidir, car pendant le même laps de temps ils gardent entièrement le lit.")

**40. Sulphaturia and Sulphated Saline Injections.**—Achard supplements his communication on the retention of chlorids in certain diseases, mentioned above, with the statement that the sulphates behave differently from the chlorids in this respect. There is no retention of the sulphates and they are more liable to induce diuresis.

**43. Bloodless Method of Treating Congenital Luxation of the Hip-Joint.**—Ghillini has now had an experience of 100 cases treated by his method, which he asserts is the reverse of the usual procedure. He aims to place the hip in such a position that the head of the femur rests against the place where the acetabulum normally should be. The new joint thus obtained does not resemble a normal joint anatomically, but behaves exactly like one. The functional results have been perfect. When the head of the femur is displaced upward, for example, he twists the thigh into exaggerated abduction. When the displacement is downward, he twists the thigh in adduction. For forward displacement he twists it in inward rotation, and for backward displacement in outward rotation. In case of a complex deformity, such as backward and upward displacement, he twists the thigh in outward rotation and abduction. He follows Lorenz's directions for after-treatment for six to twelve months.

**45. Points in Treatment of Ectopia of the Testicles.**—Coudray has found thyroid treatment effectual occasionally and urges trial of it in every case before resorting to other measures. Treatment should be commenced as early as the age of 2 or 3. About 5 cc. a day of thyroid extract should be given to boys under 3, and 10 cc. after this age, gradually increasing to 15 and 20 cc. If no results are apparent in the course of two or three months, this medication should be supplemented by manipulative measures for four or five minutes a day. This combination has proved very effective in his experience with retention in the inguinal region. When the testicle is below the ring and the cord can easily be stretched, a double Y bandage will be found useful. Treatment on these lines is liable to be successful under 10 or 12. After this age it may induce hernia or hydrocele. Bloody intervention is indicated only in case of failure of these measures.

**48. "Growing" Coxa Vara.**—Froehlich points out the resemblance between the coxa vara which is due to the rapid growth of the subject, and tarsalgia. Both are characterized by pain, muscular contraction, deformation of the bones and sometimes arthritis of the dry type. He has been very successful in curing the coxa vara by resection of the great trochanter and immobilization in bed for six weeks.

**65. Metastatic Cancer in Internal Genitalia.**—Römer describes the danger of mistaking a metastatic cancerous affection of the internal genital organs for a primary lesion. He urges that these organs should be carefully examined in operating on account of cancer elsewhere in the abdomen, and that they should be removed on the slightest suspicion of pathologic alteration. In performing a primary operation on these organs the abdomen should be carefully searched to discover indications of a tumor elsewhere which may in fact prove to be the primary lesion.

**69. Improved Technic for Operating on Cancer of the Rectum.**—The modification proposed by Jaffe is for the purpose of resting the intestine while it is healing. He draws the upper stump of the rectum out through an incision just below the tip of the spine, and fastens it temporarily in this artificial anus. Tissue gradually forms to connect the distal stump with the side wall of the rectum passing above it to the artificial anus. After the healing is complete, the walls of the distal stump are sutured to the side wall of the proximal stump above. When all this is healed, a hole is made in the side wall of the

proximal stump between the points where it is sutured to the distal stump. The course of the fecal matters is thus diverted once more to its normal route and the artificial anus is then closed.

**71. Sympathectomy in Exophthalmic Goiter.**—Balacescu reports 17 cases of exophthalmic goiter treated by total, bilateral resection of the cervical sympathetic. The results are 10 cured; 2 cured but with recurrence since, and 5 improved. The patients have been under observation twenty days to two years. He considers it comparatively harmless, and the most effective of all operative methods of treating this disease.

**73. Extensive Resections of Intestines.**—Payr thinks that the peculiarly powerful bactericidal action of the fluid which collects in a hernia or transudate is a kind of rampart against the bacteria which pour into the peritoneal cavity in cases of ileus from strangulation and similar conditions. The exceptional bactericidal power of the collected fluids in such circumstances may explain the benefits derived from Bier's artificial active and passive congestion. Payr suggests the possibility of artificially inducing a transudate or "hernia water" as a means of combating acute and chronic inflammation in abdominal affections. He reviews 35 cases of extensive resection of the intestines. In 12, more than 200 cm. were excised. About 310 cm. of the ileum were removed in one patient who is perfectly well now after several years. In another 330 cm. were resected. A patient died immediately in collapse after resection of 365 cm., but the fatal termination in this case was not necessarily the result of the resection.

**81. Dissociated Venous Pulse.**—Ascoli has observed two cases in which the negative pulse beat was more frequent and regular than the pulse in the carotid. Study of these cases has demonstrated that the auricles and the ventricles are able to work dissociated; and that dissociation is possible between the action of the right and of the left heart. The auricle contracted more frequently than the ventricle in the cases observed. Part of the contraction starting in the auricle was arrested at the auriculo-ventricular opening ("blocked heart"). This fact suggests that the cardiac impulse originates in the auricles.

**85. New Local Anesthetic.**—Von Noorden recommends the ester of para-amido-benzoic acid—the substitute for orthoform—as a harmless and effective anesthetic, free from the irritating properties of orthoform. It is more commonly known as anesthesin, and he reports a number of cases of pruritus vulvae, hyperesthesia of the throat, hemorrhoids, etc., in which he was agreeably surprised by its action.

**88. New Method of Testing the Gastric Functions.**—By the technic which Sahli describes it is possible to obtain more exact information in regard to the digestive functions of the stomach than has hitherto been possible. The substance he orders for the test breakfast is a gruel made of 25 gm. flour, 15 gm. butter and 350 c.c. of water, salted to taste. The subject eats with a spoon 300 c.c. of this palatable "flour soup," after his stomach has been rinsed. An hour later the contents of the stomach are siphoned out. The stomach is then rinsed again, while light massage is applied, as Mathieu advises, to bring the last scraps of the food. The gruel does not become materially altered in the stomach, and is thus peculiarly adapted for this kind of research. The acidity of the stomach contents can be determined from the siphoned out gruel. The proportion of fat in it is compared with that of the 50 c.c. kept for control. He tests for fat with the centrifugalizer and Gerber's butyrometer, which is a small instrument in current use for testing milk. The gruel contains no lactic acid, and hence it is a reliable test for the production of this acid in the stomach. It is possible by this procedure to determine the total acidity as well as an excess or deficit of acid, also the quantity and quality of the pepsin, rennet, digestion of starch, etc. The average in five healthy persons tested was 124 gm. of stomach contents siphoned out one hour after ingestion of 300 gm. of the gruel. This was made up of 72 gm. of gruel, 52 gm. of gastric juice and 3.5 per 1000 of hydrochloric acid. It proved possible by this means to diagnose, 1, excessive or deficient secretion or acidity, with or without excessive motor function; 2, normal

secreting power with deficient acidity and hypermotility; 3, diminished motility with diminished acidity and secretion, and 4, diminished motility with hypersecretion and anacidity. Further experience will probably reveal new combinations of disturbed functions that can be detected by this means. Already it has been established that hypersecretion and hyperacidity may occur without primary disturbance in the motor function or stenosis of the pylorus. The facts observed also suggest the necessity for laxatives or lavage of the stomach in the cases of impaired motor function and for an alkali or some preparation of belladonna in case the secretions need regulating, or a meat extract or bitters to stimulate them.

**90. Implantation of Tendon into Bone.**—The late Professor Wolff delivered this address at Berlin in December. He described some cases in which he had cured deformities by implanting the sound tendon directly in the bone. A mere incision of the bone is enough in the case of children, but he digs a groove for the tendon in a mature bone. By this transplanting of the tendon in a new spot, extremely fine functional results have been attained.

**91. To See the Outline of the Stomach without Artificial Aid.**—Knapp has the subject recline on the table with the abdomen exposed and breathe quietly. The physician brings his eyes on a level with the surface of the abdomen and watches the waves caused by the respiration. He will soon recognize a fine line which glides along during inspiration and which he will establish is the curvature of the stomach. The point where this line stops during inspiration is marked on the abdomen. The outline of the stomach thus defined is corroborated by light percussion on two fingers held close together, but with the line between them. The sound will be different from each finger if one is inside and one outside the limit of the stomach.

**101. Importance of Quinin in Treatment of Wounds.**—Marx proclaims that a .1 or .2 per cent. solution of quinin arrests the growth of the pyocyanus, staphylococcus aureus and anthrax and mesentericus bacillus. The germs that do not form spores were killed in a 1 to 1.5 per cent. solution in thirty to sixty minutes, and the anthrax and mesentericus spores in twenty-four hours' exposure to a 1.5 to 2 per cent. solution. He has recently called attention to the value of quinin as a styptic. It induces agglutination and coagulation so that it is able to arrest any parenchymatous hemorrhage in local applications. He keeps a solution of the hydrochlorate in 3 parts rectified spirits and 100 parts water, always ready for use in operating, applying it on a tampon to the bleeding surface. Quinin has also a deodorizing action, and he has never witnessed any untoward consequences from its local application. He is now studying its use in general septic affections, erysipelas, phlegmons, etc. He warms the solution to body temperature to thoroughly dissolve the quinin. If applied very long it induces a "coagulation necrosis," which may prove useful in some cases, but should be avoided in others.

**124. Agglutination of Red Corpuscles by Serum from Malarial Subject.**—Healthy serum has no agglutinating effect on the red corpuscles of healthy blood, but the serum acquires this power in disease. It is much more marked in serum from a malarial subject than in any other affection. Administration of quinin arrests this agglutinating power and may prove valuable as a differentiating measure.

**130. Acetic Acid in Alcohol for Treatment of Wounds.**—Gaetano's tests have convinced him that a 20 per cent. alcoholic solution of acetic acid is the most efficient disinfectant at our command for the treatment of wounds.

**131. Delirium in Croupal Pneumonia.**—Brancati succeeded in isolating a toxin from cultures of the pneumococcus which is evidently a neurotoxin. It causes paralysis in animals and delirium in man.

**132. The Pancreas in Relation to Tuberculosis.**—Italia was able to demonstrate that an infusion of pancreas tissue injected into susceptible animals simultaneously with virulent cultures of the tubercle bacillus, prevented the infection of the

animals. When injected after the animals had been inoculated with the bacilli, it cured localized tuberculosis. He believes that the pancreas contains a tuberculosis antitoxin.

**156. Banti's Disease.**—Gruzdoff describes 3 cases personally observed and concludes from them and the cases that have been published that the unconditional fatal termination without an operation imposes splenectomy as soon as the diagnosis is established. The small number of cases on record renders it difficult to define the disease exactly. We must include in it certain very rare forms of cirrhosis of the liver like two of the personal cases described. He adds that further study of Banti's disease can not fail to throw much light on cirrhosis of the liver in general.

**171. Involvement of the Ovaries in Epidemic Mumps.**—Troitzky found that the genital glands were affected by the mumps infection in 13 out of 33 little patients. The region over the ovaries was sensitive to pressure and more or less painful, and he suggests that possibly mumps may be responsible for some of the pathologic changes observed in the ovaries in later life. He recommends that this region should be investigated in girls and local measures applied at once at the slightest symptom of inflammation of the ovaries or their environment. By warding off or dispelling inflammation in the early stage we can safely guarantee that the ovaries will pass unscathed through the disease.

**173. Occlusion of Auriculo-Ventricular Opening.**—Mendez attributes the occlusion of the opening in this case to a fetal endocarditis after the parts were nearly formed. The patient was a man of 26, well developed, but always troubled with recurring symptoms of asystolia. Seven cases are on record of occlusion of this opening from lack of development, the oldest subject 10 years of age, and ten cases in which it was evidently due to a fetal endocarditis. Six were under 2 years of age, one 8, one 21, one 28, and the present case.

**177. Growing Together of the Jaws.**—Castro reports the case of a man 23 years of age whose jaws had grown inextricably together as the result of noma after measles in childhood. He was able to eat only liquid food, and this through a small opening where two canine teeth were missing. General and even local anesthesia were impossible under these conditions, and the cheeks were first detached from the jaws. When this wound had healed the interlaced teeth were pulled and the jaws pried apart, until comparative function was restored on the left side.

**178. Treatment of Detachment of the Retina by Injections of Sodium Chlorid.**—Castresana announces that injections of a concentrated solution of sodium chlorid cure detachment of the retina by the strong osmotic currents and the slight irritation with consequent adhesions which they induce. Starkle has recently reported 23 cases thus treated, resulting in 6 complete and 10 partial cures. He used a 4 to 10 per cent. solution which Castresana does not consider sufficiently powerful. He would probably have been still more successful if he had injected a saturated solution of the sodium chlorid such as Castresana recommends. He reports several patients treated in this way with the cure of all the recent cases. Detachment of long standing is incurable. In one patient the detachment had occurred four years previously in one eye and six months in the other. The first eye was not affected, but the detachment was entirely cured in the second eye with restoration of vision. He injects beneath the conjunctiva 2 gm. of a saturated solution of sodium chlorid to which two drops of acoin have been added. The injection is rather painful and causes considerable chemosis for a few hours, with irregular pulse and a tendency to vomit, but all these symptoms passed away in the course of twelve hours and the reaction was very slight to the second injection, which he found necessary in a few cases. No results were noted after the injections in two cases of six and two years' standing. He administers potassium iodid as an indispensable adjuvant to the local treatment. He considers this method of treating detachment of the retina as the most rational at our command. He illustrates the eye before and after treatment in the two perfectly cured patients.

### New Patents.

Patents of interest to physicians, etc., May 6 and 13:  
 699,166. Apparatus for purifying air. David Grove, Berlin, Germany.  
 699,401. Exercise device. Wm. F. Lott, East Orange, N. J.  
 699,255. Inhaler. Ernest Stevens, Philadelphia.  
 699,598. Burner and inhaler. Wm. R. Warner, Vergennes, Vermont.  
 699,637. Respirometer. Albert E. Aldrich, Lexington, Ky.  
 699,797. Hernial truss. Per Johan Fredin, Bridgeport, Conn.  
 700,139. Attachment for uterine packers. John E. Fuller, Mansfield, Mass.  
 699,916. Body kneader. Charles Gerling, Burlington, Iowa.  
 699,677. Medical battery. Fredric Greer, Chicago.  
 699,757. Child's teething nipple. Wm. Howell, Brooklyn.  
 699,897. Analgetic bandage. Thomas L. Ray, Fort Worth, Tex.  
 699,717. Sterilizer. Sam G. Scanlan, Chicago.  
 699,778. Water bag. Hubbard H. Upham, New York City.

## The Public Service.

### Army Changes.

Movements of Army Medical Officers under orders from the Adjutant-General's Office, Washington, D. C., May 8 to 14, 1902, inclusive:

Daniel M. Appel, major and surgeon, U. S. A., detailed to represent the Medical Department of the Army at the Fifty-third Annual Meeting of the American Medical Association, to be held at Saratoga, N. Y., June 10 to 13, 1902, in addition to others previously designated.

James K. Ashburn, contract surgeon, relieved from further duty at Fort Grant, Ariz., and on expiration of present leave of absence will proceed from Batavia, Ohio, to Fort Crook, Neb., for duty at that post.

R. Emmitt Austin, contract surgeon, now at Fort Robinson, Neb., is relieved from further duty in the Department of Cuba, and will report to the commanding officer of that post for duty.

Harry D. Belt, contract surgeon, leave of absence for one month granted; he is relieved from further duty in the Department of Cuba and on his arrival at Fort Robinson, Neb., will proceed to Fort Keogh, Mont., for duty at that post.

John D. Brooks, contract surgeon, to proceed from Washington, D. C., to St. Paul, Minn., for assignment in the Department of Dakota.

H. L. Brown, contract surgeon, now at Fort Sheridan, Ill., will report to the commanding officer of that post for duty.

Lawrence C. Carr, major and surgeon, Vols., leave of absence for one month granted.

James R. Church, lieutenant and asst.-surgeon, U. S. A., to report on board the U. S. Cruiser *Dixie*, New York City, for the purpose of proceeding to Martinique, to distribute medical supplies and render necessary medical attendance to the inhabitants at that place, returning thereafter to his proper station.

Jere B. Clayton, lieutenant and asst.-surgeon, U. S. A., as Church, stated above.

Douglas F. Duvall, lieutenant and asst.-surgeon, U. S. A., leave of absence for one month granted.

James C. Gregory, contract surgeon, member of an examining board at Fort Myer, Va.

W. Church Griswold, contract surgeon, now at Albany, N. Y., to proceed to San Francisco, en route for service in the Division of the Philippines.

Valery Havard, lieutenant-col. and deputy surgeon-general, is detailed to represent the Medical Department of the Army at the Second International Conference for the Prevention of Syphilis and Venereal Diseases, to be held at Brussels, Belgium, Sept. 1 to 6, 1902. On the adjournment of the Conference he will return to his proper station, Fort Monroe, Va.

Charles F. Kieffer, captain and asst.-surgeon, U. S. A., leave of absence for one month granted.

Louis M. Maus, lieutenant-colonel and deputy surgeon-general, is relieved from further duty in the Division of the Philippines, to take effect about June 30, 1902, and will then repair to Washington, D. C., and report for instructions to the Surgeon-General of the Army.

Donald P. McCord, captain and asst.-surgeon, Vols., leave of absence extended one month.

H. C. Moses, contract-surgeon, leave of absence from the Department of California extended one month.

Joseph Pettyjohn, contract surgeon, previous orders directing him to proceed to Augusta, Ga., for annulment of contract revoked.

John J. Riley, lieutenant and asst.-surgeon, U. S. A., as Church, stated above.

Gideon McD. Van Poole, lieutenant and asst.-surgeon, U. S. A., now under treatment at the Army and Navy General Hospital, Hot Springs, Ark., will report to the commanding officer of that hospital for temporary duty.

### Navy Changes.

Changes in the Medical Corps of the Navy for the week ending May 17, 1902:

Surgeon W. F. Arnold, detached from duty at Guam, and ordered to the Naval Hospital, Yokohama, Japan, for treatment.

Asst.-Surgeon W. H. Bell, detached from the Naval Hospital, Norfolk, Va., and ordered to duty on board the *Chesapeake*, when that vessel goes in commission.

Drs. E. M. Brown, H. F. Shrine, J. P. Traynor and R. E. Hoyt, appointed assistant surgeons, May 8, 1902.

### Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned

and non-commissioned officers of the U. S. Marine-Hospital Service for the seven days ended May 15, 1902:

Surgeon R. D. Murray, granted leave of absence for 25 days from June 1.

Surgeon Eugene Wasdin, leave of absence for seven days, from May 2, 1902, under Paragraph 179 of the regulations, amended so that said leave shall be for three days.

P. A. Surgeon G. M. Guiteras, Bureau order of May 5, 1902, directing him to proceed to Philadelphia, amended so that he shall proceed to Cienfuegos, Cuba, for temporary duty; upon completion of temporary duty at Cienfuegos to proceed to Philadelphia.

Asst.-Surgeon Ilii Hastings, detailed to represent the service at meeting of Southern California Medical Society at Idyllwild, May 22 and 23.

Asst.-Surgeon John McMullen, granted leave of absence for fourteen days from May 14. Relieved from duty at Boston, and directed to proceed to London, England, for duty in the office of the U. S. Consul-General.

Asst.-Surgeon J. M. Holt, relieved from duty at St. Louis, and directed to proceed to Honolulu and report to medical officer in command for duty, stopping en route at San Francisco quarantine for special temporary duty.

A. A. Surgeon Francis Duffy, granted leave of absence for six physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon H. W. Sawtelle, chairman; Asst.-Surgeon L. P. H. Bahrenburg, recorder.

### Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, U. S. Marine-Hospital Service, during the week ended May 17, 1902:

#### SMALLPOX—UNITED STATES.

Alabama: Mobile, May 10, 21 cases.

California: Los Angeles, April 19-May 3, 11 cases; San Francisco, April 27-May 4, 7 cases.

Colorado: Denver, April 28-May 5, 3 cases.

Florida: Jacksonville, April 26-May 10, 4 cases.

Illinois: Belleville, May 3-10, 3 cases; Chicago, May 3-10, 10 cases, 1 death; Galesburg, May 3-10, 5 cases; Peoria, April 1-30, 26 cases.

Indiana: May 3-10, Evansville, 1 case; Indianapolis, 6 cases.

Kentucky: Covington, May 4-11, 13 cases; Lexington, May 3-10, 1 case.

Maine: Portland, May 3-10, 1 case.

Maryland: Baltimore, May 3-10, 5 cases.

Massachusetts: May 3-10, Boston, 28 cases, 6 deaths; Brockton, 1 case; Cambridge, 1 case; Everett, 2 cases; Lowell, 2 cases; Malden, 2 cases; Newton, 1 case; Northampton, 1 case; Somerville, 1 case.

Michigan: Detroit, May 3-10, 2 cases; Grand Rapids, April 26-May 10, 7 cases.

days from May 19.

A. A. Surgeon J. A. Rowles, granted leave of absence for thirty days from May 12.

#### BOARD CONVENED.

Board convened at the marine hospital, Chicago, May 31, for the

Minnesota: Winona, April 26-May 3, 1 case.

Missouri: St. Louis, May 4-11, 48 cases.

Montana: Butte, April 27-May 4, 4 cases.

Nebraska: Omaha, May 5-12, 29 cases.

New Jersey: Camden, May 3-10, 1 case, 2 deaths; Hudson County, including Jersey City, April 27-May 4, 32 cases, 6 deaths; Newark, May 3-10, 40 cases, 7 deaths; Passaic, April 26-May 10, 2 cases; Plainfield, May 3-10, 3 cases.

New York: New York, May 3-10, 58 cases, 9 deaths.

Ohio: Cincinnati, May 2-9, 11 cases; Cleveland, May 3-10, 4 cases; Toledo, May 3-10, 1 case; Youngstown, April 19-26, 1 case.

Pennsylvania: Columbia, May 5-12, 5 cases; Erie, May 3-10, 3 cases; Philadelphia, May 3-10, 24 cases, 2 deaths; Pittsburgh, May 3-10, 17 cases, 1 death; York, April 1-30, 3 cases, 1 death.

South Carolina: Charleston, May 3-10, 2 cases; Greenville, April 26-May 3, 1 case, 1 death.

South Dakota: Sioux Falls, May 3-10, 1 case.

Tennessee: May 3-10, Memphis, 21 cases, 1 death; Nashville, 1 case.

### NOTES ON ANEURISM.

WILLIAM OSLER, M.D.,

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY.  
BALTIMORE, MD.

#### SUMMARY.

1. Arteriovenous Aneurism of the Subclavian Vessels.
2. The Humming-top Murmur in Thoracic Aneurism.
3. On the Value of the Fluoroscope in the Diagnosis of Obscure Cases of Thoracic Aneurism.
4. On the Importance of Careful Inspection of the Chest in Thoracic Aneurism.

#### 1. ARTERIOVENOUS ANEURISM OF THE SUBCLAVIAN VESSELS.

The elaborate study by Matas, published in the early numbers of *THE JOURNAL* this year, and his analysis of the 15 cases on record, add interest to the following report:

CASE 1.—CLINICAL SUMMARY. *Bullet-wound of the right subclavian artery and vein in January, 1900. Formation of arteriovenous aneurism. Operation not advised. Good health March, 1902.*

Edward S., aged 29, of Kentucky, was sent to me by Dr. Alderson on April 9, 1900, with the following history: On the night of Jan. 5, 1900, he was shot, receiving four bullets. One entered the left shoulder and is now imbedded in the upper portion of the spine of the scapula and gives no trouble. One entered about the middle of the back of the left arm and passed inwards and downwards to inside the condyle of the humerus, where it was deflected across the bend of the elbow and down the forearm, making its exit about the upper third, injuring the ulnar nerve. The third bullet entered the left side a little behind the mid-axillary line between the ninth and tenth ribs. It apparently did not penetrate the chest at all. The fourth entered just about the middle of the fold of the left trapezius, passed inwards and downwards in front of the spine and came out under the right clavicle. The wounds healed rapidly. He had at first some difficulty in swallowing, but he has gradually been getting well. There was at once considerable swelling in the neighborhood of the clavicle, with marked pulsation, a thrill and a bruit.

*Present Condition.*—He looks well. Tongue is clean. Chest is well formed. Immediately above the free margin of the middle of the left trapezius there is a bullet-wound, the point of entrance of the ball which caused the aneurism. The left clavicle stands out a little more prominently than the right. The right clavicle is just visible. The supraclavicular fossa is occupied by a pulsating swelling which causes a marked prominence between the sterno-clavicular margin, extending outward a distance of about 7 cm. It does not lift the sterno-cleido-mastoid muscle, the sternal outline of which is plainly marked. The sternal notch is plainly marked. Above, the swelling extends for fully 7 cm. The pulsation is visible over the whole tumor. From behind it is very noticeable. On palpation there is a marked thrill, continuous, but with systolic

intensification, felt and heard over the whole tumor, and felt up the neck fully 7 cm. from the clavicle. It is well felt on deep pressure to the right in the sternal notch, not felt on the clavicle. The tumor forms a distinct pulsating mass about the size of, or a little larger than, an egg, quite painless. No thrill is felt below the clavicle or over the body of the heart or on the sternum. Apex beat in nipple line; no increase in area of cardiac flatness. On auscultation both sounds are loud and clear at apex and over the whole precordia. Everywhere, too, from the apex up, increasing in intensity, is heard a humming-top murmur, with marked systolic intensification. At the sternum it is very loud, and over the aneurism reaches its maximum intensity. An interesting feature is that he feels the pulsation in the left ear, not in the right. The murmur is of extraordinary intensity, heard up and down the neck, heard along the axillary artery to the elbow. The systolic murmur is very intense, and the whole diastole is occupied by a wheezing, wiry Aolean murmur. In the recumbent posture the tumor does not look larger, and the thrill is not so evident. The pulsation in the subclavian below the clavicle on the left side is visible. On the right side it is not visible. There is a marked difference between the pulse in the radial arteries; the right is feeble, only just to be felt. The brachial pulse can be felt. The axillary can be felt, much feebler on the right side than on the left. The carotid on the right side is full and easily felt. There is no thrill in it on palpation. There is no difference in the pulse in the temporal arteries. The bullet was located with the *x*-rays, and can be felt just below the clavicle.

There is no question that the bullet in this case has nicked the subclavian artery and vein, causing arteriovenous aneurism. The man's general condition was good, and as he was improving I counseled very strongly non-interference. Subsequently he saw several surgeons, some of whom were anxious to operate, but fortunately he escaped them. Since then he has been doing well, and I heard from his physician, March, 1902, that the tumor is smaller and he is able to do quiet work and has little or no inconvenience.

The question of operation in these cases has been very fully discussed by Matas in his exhaustive study above referred to. Of his collection of 15 cases 4 were operated on, 3 within 12 days of the injury, and one 32 years after, which was the only one fatal. Unfortunately, 6 of the 11 cases passed out of observation within a few weeks or months after the injury, while the lesion was still active. The ultimate result of the other cases shows that the condition may remain quiescent for a long period of years. In a few instances there were serious disturbances of the circulation and innervation of the hand and arm, while in one case (Watmann's), after a latent period of thirty-one years, the lesion became active and gave rise to fatal complications.

The condition of arteriovenous aneurism has interested me for a number of years, having had under observation at intervals a man whose case I described in the *Annals of Surgery*, 1893. At that time he was

twenty-five years of age. When fifteen he had fallen and a lead-pencil in his waistcoat pocket penetrated the axilla, causing an arteriovenous aneurism. He had remained very well, had been very active and strong, had rowed in boat races. I heard of this patient not many months ago. He had served through the South African war, so that his general condition must have remained good. The aneurism has persisted now for more than twenty-three years.

Arteriovenous aneurism is so rare a lesion that even surgeons of large experience are often a little perplexed as to the best course to follow. I am very much impressed with this in the extraordinary differences of opinion given to the young man with the lesion high up in the axillary artery. The conclusions of Matas which are strongly in favor of non-interference may be quoted: "The statistics which we furnish in this paper—the most complete list of the reported instances of this rare lesion which has thus far appeared—tend to confirm the arguments of the 'let-well-enough-alone' policy, in so far as they demonstrate that in at least 11 of the 15 cases the patient survived the immediate effects of the injury and of the arteriovenous aneurism that followed it for variable and often long periods of time."

## 2. THE HUMMING-TOP MURMUR IN THORACIC ANEURISM.

In September, 1888, there was admitted under Dr. Pepper's care at the University Hospital, Philadelphia, a Chinaman, whose case I had frequent opportunities to study with Dr. Crozier Griffith. The case was reported by Pepper and Griffith in the "Transactions of the Association of American Physicians," Vol. V. The remarkable features were cyanosis, and a murmur of extraordinary character, heard loudest at the aortic cartilage and accompanied with a thrill. As described by the writers, the murmur was "loudest and highest pitched with the cardiac systole; it died away very considerably during the diastole, and lowered its pitch by several tones, to rise again both in volume and pitch with the next systole. It was thus continuous, and had a distinctly venous quality, although unlike a venous hum in that it was distinctly rhythmic." At the autopsy there was found a small aneurism of the ascending aorta which communicated with the superior vena cava by an opening three-fourths of an inch in length. The case made a very definite impression upon me, and I have since learned to recognize the murmur as almost pathognomonic of abnormal communication between the chambers of the heart or between the great vessels at the root of the neck, or of an aneurism at the aorta with the vena cava or pulmonary artery. More definitely, the cases in which I have recognized it have been congenital heart disease with persistence of the ductus arteriosus, cases of imperfection of the ventricular septum, and in the two cases here given:

**CASE 2.—CLINICAL SUMMARY.** *Young man. Syphilis 3 years before admission. Cough. Shortness of breath. Aneurismal tumor to right of sternum. Loud, continuous murmur with systolic intensification. Postmortem. Communication of a large branch of the right pulmonary artery with the aneurismal sac.*

Joseph M., aged 30, admitted first on July 29, 1901 (Med. No. 13,212), complaining of shortness of breath, cough and pain in the chest. An important point in his history was that three years ago he had syphilis. He had been a heavy drinker and a heavy smoker. His illness began in October, 1900, with a cough, which was dry and hard and troubled him very much at night. He had shortness of breath from the beginning. These symptoms increased throughout the winter. He had pain first in February.

On his first admission the signs of aneurism of the thoracic

aorta were very well marked—a visible bulging with pulsation to the right of the sternum; no thrill; very exaggerated diastolic shock; flatness over the pulsating area. Dr. Futeher, who dictated the note, described the heart sounds as clear and a very faint soft systolic murmur along the left sternal border and over the prominent part of the pulsation. There was no diastolic murmur. The patient was given a gelatin injection and kept at rest. On my return in September I saw him, and he then had very much the symptoms described by Dr. Futeher when first admitted.

Then he returned on December 31. He had been in the country and had become very much worse, having attacks of dyspnea and weak spells. The pulsating tumor was larger. There was a wider extent of flatness. The most remarkable change was on auscultation over the sac. The diastolic shock was extreme and there was a feeble thrill. There was a very loud, continuous murmur occupying the entire cardiac cycle, with a great deal of echoing reverberation and marked systolic intensification.

The sac was evidently so large and so far out that, while I recognized the murmur as the kind heard with abnormal communication, I must say I thought it possible that this remarkable whirring, continuous murmur might be produced in a very large sac.

The patient died Jan. 10, 1902. The anatomic diagnosis was arteriosclerosis, aneurism of the arch of the aorta, compression and atelectasis of right lung. On the posterior wall of the sac, where it had pressed into the lung, one of the main branches of the right pulmonary artery, fully as large as the little finger, opened directly into the sac.

**CASE 3.—CLINICAL SUMMARY.** *Syphilis two years before observation. Cyanosis. Shortness of breath. Great congestion of the veins of the upper-half of the body and of the arms. Gradual development of compensatory circulation in the mammary and epigastric veins. Over the manubrium and aortic regions a continuous murmur with marked systolic intensification, limited to the area about the aortic cartilage and the middle of the manubrium. Death. No Autopsy.*

Jos. S., aged 39, an iron-molder, applied at the dispensary of the Johns Hopkins Hospital Dec. 7, 1889. He had been ill since January, complaining of giddiness, cough, shortness of breath, swelling of the feet and a congested and bluish condition of the face, which became aggravated when he attempted to do heavy work. He is a thick-set, well-built, muscular man. He had a chancre two years ago. There is no history of rheumatism or chorea, but in September, 1888, he was in bed three weeks with some obscure pulmonary trouble.

**Physical Examination.** Face is swollen and reddish; lips and ears are cyanotic. Conjunctivæ watery. The tongue is clean, deeply congested and the whole of the pharyngeal mucosa is intensely engorged. Chest is large, antero-posterior in diameter, deep. The skin, covering the entire thorax and of the arms is congested. The venules along the line of the diaphragm and in the lateral region of the chest are dilated. The neck is thick, supra-clavicular spaces distended, sternal notch obliterated. The breathing is quiet, 24 to the minute. The apex beat is indistinct, but a feeble impulse is visible in 5th in nipple line and there is throbbing in the epigastric notch. There is a feeble shock of the first to be felt at the apex, but there is no pulsation at the base on deep pressure. There is no dulness on the manubrium sterni and the superficial area of heart dulness is not increased. On auscultation there is a systolic murmur at apex, propagated to the back. The second sound is ringing. Along the left sternal border the systolic murmur becomes more intense. Over the manubrium there is a loud murmur of very peculiar character, not like an ordinary aortic systolic, short and rough, but a murmur which seems continuous and during the systole greatly intensified. The second sound at the base is clear and ringing. The radial pulses are equal; pupils equal. There is no brassy cough. On examination of the chest a few piping râles with prolonged expiration were noted.

The patient was seen on four occasions during the next month. The cyanosis and shortness of breath had increased. On January 7 I made the following note: Much worse since last seen on the 2d. The face is much swollen and absolutely

blue, looking like that of a man who had been strangled. The mucous membrane of the pharynx intensely livid. Eyelids swollen; conjunctivæ deeply engorged. The neck is enlarged; the external jugular is prominent. The upper part of the chest and both arms are swollen but not edematous. The veins of the arms are full. The whole subcutaneous tissue feels thickened and infiltrated. The right side and the right arm are more swollen than the left. In the lower chest zone the venules are greatly enlarged, but no large mammary veins are visible. When stripped the contrast between the upper and the lower parts of the body is remarkable. The engorgement goes as far as the lower abdominal zone. The legs are quite pale. The amount of subcutaneous infiltration is such that the superficial veins are not visible. The apex beat is indistinct. There is a systolic shock. The area of cardiac dullness is not increased. In 5th interspace below nipple, there is a loud systolic murmur not obliterating the first sound, at aortic cartilage and on manubrium the same remarkably loud, continuous murmur is heard, with systolic intensification; second sound clear and ringing. The systolic murmur is heard to left and right two inches from the sternum, but the continuous murmur is only heard at the more limited area about the aortic cartilage with a maximum at mid-manubrium.

The radial pulses were equal, 98; respiration quiet. The subjective sensations of the patient are remarkable. He says that he feels comfortable with the exception of the feeling of distension in face, chest and arms. It is extraordinary how slight is the distress in breathing in a man presenting a condition of such extreme cyanosis. He says that one of his chief annoyances is the shock which his appearance gives to his friends. He is not drowsy. His intellectual condition is perfect. He sleeps at night with his head high.

About two weeks subsequent to this visit we heard that the patient had died; but his wife refused an autopsy. She said he got progressively worse and even more cyanotic. He was taken to the city hospital, but whether he died there or at his house she did not say.

This patient presented the characteristic features which Pepper and Griffith describe in an analysis of some 29 cases of communication between an aneurism of the aorta and the superior vena cava, more particularly the extreme cyanosis of the face and upper parts of the body, with evidences of obstruction of the circulation in the tributaries of the superior vena cava. They regard the murmur as characteristic of communication between an artery and a vein, and state that it was first described by Thurman in 1832-33. The characters are:

1. It is continuous, occupying both the systole and diastole.

2. There is a systolic reinforcement, often of great intensity.

3. The venous quality of the murmur, resembling the characteristic venous hum in the jugular and the murmur over the thyroid in Graves' disease.

The quality varies. It may be a buzzing or it may have a remarkable, sonorous, vibratory character, or, again, it may be a churning or purring murmur. Ord describes it very well as a long continuous humming murmur, never ceasing, but varying in intensity, more sonorous during systole, fainter during diastole. To Thurman the credit appears to be due for the recognition of a murmur of this quality as pathognomonic of arterio-venous aneurism. The question has been very fully discussed by Sir William Gairdner in the Glasgow Hospital Reports, 1899, in the report of an interesting case in which a small aneurism of the ascending portion of the arch communicated with the pulmonary artery.

### 3. ON THE VALUE OF THE FLUOROSCOPE IN THE DIAGNOSIS OF OBSCURE CASES OF THORACIC ANEURISM.

CASE 3.—CLINICAL SUMMARY. *Cough and dyspnea for six months. Much emaciation. Flatness to left of sternum. Diagnosis of mediastinal sarcoma. Examination by fluoroscope*

*showed a characteristic pulsating tumor. Subsequent slight pulsation of the thoracic wall. Wiring of the sac. Hemoptysis. Death.*

On Jan. 15, 1902, I was consulted by Mr. T. R. F., who had been complaining of cough for six months, loss in weight and pains through the chest. I was impressed at once with the expression of great distress and anxiety in the poor fellow's face. He looked worn and exhausted with suffering, and he said that he had not been able to lie down for some weeks, and had had nights of indescribable anguish owing to the orthopnea, pain and sense of smothering. I was impressed at once with the noisy, stridulous, tracheal character of the breathing. He had been a bartender, had taken alcohol freely, and had had venereal sores at different times; the strong probability is that he has had syphilis. He thinks that for a year he has had some cough, but for six months there have been shortness of breath, loss of weight and pain in the chest. About three months ago his voice changed. He has had no spitting of blood. Of late he has had frightful paroxysms of pain and orthopnea, particularly at night. He had consulted a number of physicians in New York and elsewhere, and the diagnosis had been made of mediastinal sarcoma.

On examination the chest was well-formed, expansion good and seemed equal on both sides. No abnormal area of pulsation was noticeable; no throbbing in the sternal notch. There was an area of impaired resonance in the first, second and third left interspaces and over the central portion of the manubrium. The point of maximum impulse was in the fifth interspace, 10½ cm. from the mid-sternal line. The cardiac flatness was not increased. There was a soft systolic murmur at the apex; the second sound was clear and without special accentuation over the area of dullness. The pulse was of good volume; the left radial was smaller than the right. The breath sounds on the left side were less intense than on the right.

Altogether, at the first examination I was inclined to agree with the diagnosis which had already been made of mediastinal sarcoma. It seemed to me that an aneurism would by this time have shown more definite physical signs. The patient entered the Johns Hopkins Hospital that I might study his case more fully. The following additional points were then made out. First, "with the x-rays there was a large shadow seen, which extended from the upper end of the sternum to the upper border of the third rib. It did not extend to the right beyond the shadow of the vertebræ, but did to the left to about opposite a point 2/5 of the extent of the clavicle from its inner end. It was sharply defined with clear outlines, showed slight pulsation and moved very slightly to the left on deep inspiration. It could be clearly separated from the shadow of the heart. Looked at from behind it looked larger than from in front. It is worthy of note that it seemed denser and with much sharper outlines than in cases of undoubted aneurism previously examined." (Dr. McCrae.) Secondly, on the second day after admission, on getting the patient into a bright light and examining the chest critically, there was seen a distinct slight visible pulsation in the first left interspace and the left clavicle was slightly lifted. Thirdly, there was well-marked paralysis of the left vocal cord. Fourthly, the blood pressure showed the right brachial maximum 118, left brachial maximum 103. These points seemed quite sufficient to settle the diagnosis of aneurism against that of mediastinal sarcoma. It is interesting to note that there was no bruit over the pulsation; no special accentuation of the aortic second sound. The patient's condition was most distressing. The nights were passed in terrible distress and in order to reduce the blood pressure he was bled on several occasions with very great relief. On January 20 his condition seemed perfectly desperate, and as a last resort I asked Dr. Finney to wire the sac. The patient stood the operation remarkably well. The needle was inserted in the second left interspace about 5 cm. from the sternal margin over an area in which there was marked pulsation. "A medium-sized needle was inserted in a direction backward and slightly downward and inward. When the needle had been inserted about 6 cm. a pulsation was transmitted to it. It was then pushed in about 2 cm. further, when fresh blood escaped in spurts. Ten feet and seven inches

of No. 27 spring silver wire, wound large, (75 parts copper to 1000 silver, alloy) was then slowly inserted. A current of 10 ma. was then allowed to pass through the wire for one hour." The patient seemed very much benefited by the operation, and seemed for a few days decidedly improved. Then, on the night of the 17th he had a small hemorrhage. On the 18th he had a sudden profuse hemorrhage from the lungs and died in a few moments. The heart beat faintly for thirty seconds after the last respiration.

Postmortem there was found an aneurism of the transverse arch, containing mural thrombi within the sac, and the wire was within the sac. There was compression of the left bronchus, perforation into the trachea, hemorrhage into the right lung.

It is particularly in this group of aneurisms, with symptoms and no physical signs, that the x-ray examination is of such service, but we have not had a case in which it was more clearly demonstrated than in the one here noted.

#### 4. ON THE VALUE OF CAREFUL INSPECTION OF THE CHEST IN THE DIAGNOSIS OF THORACIC ANEURISM.

A bare chest, a good light and good eyes are the essentials. Routine in the examination is important. Invariably at the ward visit after the inspection of the front of patient's chest I say to the student, "What next?" and he immediately proceeds to palpation, overlooking the inspection of the back, and which, if not made in the right time, and in a routine manner, may be overlooked altogether.

Many years ago at the Girard Hotel, Philadelphia, I saw a remarkable case which illustrated the value and importance of the point. The patient had a large area of pulsation in the lower front of the chest, extending almost from one nipple to the other, with distinct prominence. There was a double murmur at the base of the heart, and the case had been regarded as one of aortic insufficiency, which condition was present. He had paroxysms of great distress and orthopnea, and there were peculiar features about the case, so that one or two of the leading physicians in Philadelphia had expressed themselves as somewhat puzzled about its nature. Fortunately, after finishing the inspection in front, I turned the patient's back to a good light, and the diagnosis was made at a glance. There was a pulsating aneurismal tumor in the left interscapular region, which had given him no pain whatever, and which had not attracted the attention of his physicians. A remarkable condition was present in this case, which I had never seen before; namely, a complete absence of the pulse in the iliacs and femorals.

At present in my wards are two cases illustrating this very well; a man (Leonard) has a wide area of impulse in the lower sternum and adjacent interspaces. He has been under observation now for nearly three years, and time and again Dr. Thayer, Dr. Fletcher and myself have discussed the possibilities. A positive diagnosis was not reached until a year ago, when a slight pulsation was seen in the left interscapular region, which has increased, and it is now quite evident that there is a large aneurism of the descending thoracic aorta.

The second case, a man aged about 35, has on inspection of the chest a very well-marked pulsation of the manubrium. The diagnosis of aneurism will be made at a glance. He has had a great deal of dyspnea and pain in the chest. On additional examination it is noted as rather remarkable that with so much pulsation on the manubrium there is little or no flatness. There is a well-marked to-and-fro friction. Inspection of the back shows in the left interscapular region slight bulging, with well-marked visible and palpable pulsation.

Sometimes the diagnosis is hidden beneath a tucked-up undershirt. Last year a robust-looking man consulted me about Nauheim: he had been told that he had heart disease, and a physician in Florida had said that his case was a very suitable one for the Schott baths. When stripped, the diagnosis was made at a glance. The head of the clavicle was lifted out of its bed with each systole, and there was a definite pulsating tumor above the sternal notch with a thrill and a loud to-and-fro murmur. In the numerous examinations he had never taken off his shirt, but had tucked it up, and consequently, nobody had ever noticed the aneurism.

Some years ago I got into trouble by too careful inspection and detecting an early throbbing in the third right interspace. A robust, strong man consulted me for cough, shortness of breath and inability to lie down at night. He had the wheezing, goose-cough, as it is called, and there was to be seen most clearly and distinctly, a pulsation to the right of the sternum. With rest, the symptoms improved and the pulsation lessened remarkably. Other physicians (among them one well-recognized authority on heart disease) assured the family there must have been a mistake, as there were no signs of aneurism. The patient improved and I saw him about for more than two years. I began to think that there had been a mistake, but subsequent events showed that the diagnosis was correct. Spontaneously, particularly after prolonged rest, the pulsation of an aneurism to the right or left of the sternum may completely disappear. I do not refer here to cases of 20 called dynamic pulsation, but to cases in which the subsequent history and autopsy has confirmed the existence of an aneurism.

#### A BRIEF SUMMARY OF THE CLINICAL, PATHOLOGIC, AND BACTERIOLOGIC FEATURES OF CUTANEOUS BLASTOMYCOSIS (BLASTOMYCETIC DERMATITIS, OF GILCHRIST),

FROM THE OBSERVATIONS OF DR. JAMES NEVINS HYDE AND THE WRITER, WITH ILLUSTRATIONS FROM THIRTEEN CASES, THREE OF THEM HITHERTO UNPUBLISHED.\*

FRANK HUGH MONTGOMERY, M.D.

ASSOCIATE PROFESSOR OF DERMATOLOGY, RUSH MEDICAL COLLEGE. CHICAGO.

The purpose of this communication is to present to the general practitioner a clinical description, illustrated by photographs of cases, of a cutaneous disorder which is probably more common than is generally supposed and which has possibly been confounded in the past with verrucous tuberculosis of the skin, with unusual forms of carcinoma, or with atypical manifestations of syphilis. For diagnostic purposes a brief description of the histopathology and of the bacteriology (in so far as it is understood) of the disorder is included.

The following description is based chiefly on the clinical, pathologic and bacteriologic study of 14 cases, 13 of which have been under more or less constant observation by us for periods ranging from four months to four years, 10 of them having been under our care for a year or longer. Of these we have studied the histopathology in 13 and obtained cultures in 11 cases. The organisms from 9 cases are at present growing under

\* Presented, in part, as a lantern-slide exhibit, to the Dermatologic Section of the American Medical Association, at St. Paul, June, 1901.

our constant observation. In addition we have had the privilege of studying clinically 1 case, histologic sections from 9 cases and organisms in 3 cases reported or to be reported by other observers.

We are indebted to our associates, Drs. Ernest L. McEwen and Oliver S. Ormsby for assistance in the examination and treatment of many of the cases here recorded. Dr. Ormsby, in particular, has done much valuable work for us in the preparation and study of histologic specimens and cultures. We wish further to express our thanks to Drs. W. L. McBride and William A. Quinn, and to Messrs. S. H. Sheldon, R. T. Woodyatt, and S. C. Emly, for various services rendered in connection with this work during the past three years. Dr. W. H. Knap has prepared for us all the photomicrographs but one.<sup>†</sup>

Following the original communications on the subject from Gilchrist and Busse, a number of cases have been observed in which cutaneous lesions of a fairly constant type were apparently due to fungi, all of which in tissue present characteristics of blastomycetes or budding fungi. In cultures the organisms in different cases have varied considerably, a few growing as yeast fungi, some showing chiefly a mycelial growth. In no reported case of this disease has the life-history of the organism been studied satisfactorily, and our knowledge of these organisms at present is too limited to warrant attempts at classification. Although for the cultural features the term "blastomycosis" is insufficient and unsatisfactory, it at least applies to the organisms as found in tissue, and it seems preferable to retain for the present the name under which so many cases have been reported, rather than to add to existing confusion by attempting to coin a new name.

#### CLINICAL ASPECTS OF THE DISORDER.

(a) *General.* The disease in its origin and career corresponds to a local infective process having a chronic course. The family and individual history of the patient evidently have little or no bearing on the disease. Of 32 accepted cases, published or unpublished records of which are available, in 5 only is there a history of tuberculosis in the family. Of the 32 individuals affected with blastomycosis, 28 gave no history or evidence of syphilis or tuberculosis. One of our patients (case not included in the present report, but to be published later) gave a history of gonorrhea, an indefinite history of syphilis, and died of tuberculosis two and one-half years after the first appearance of the blastomycosis on the face, the cutaneous disorder improving but refusing to disappear entirely under potassium iodid. Another patient (Case 7), now under treatment, has cervical adenopathy and belongs to one of the five tuberculous families mentioned above. She shows no other evidence of tuberculosis, however, and is in good general health. Another patient (Case 11) was in poor health and tuberculosis was suspected but could not be demonstrated. The fourth case in which there was an unfavorable history is that reported by Busse and Buschke, the patient having general adenopathy and other symptoms suggesting tuberculosis. In the majority of all patients the general health has been good, and in none has any constitutional disorder been discovered which could have any bearing on the origin of the cutaneous lesions.

No relation can be discovered between the disease and

the sex, occupation, nativity, or habits of the individual affected. Of the 32 patients, 21 were men and 11 women, the larger number of cases in men being due probably to their more frequent exposure to infection. While no definite relation can be recognized between the age of the patient and the disease, it may be noted that about half the cases have occurred after the fortieth year. One case began at 20 years; 6 between 20 and 30; 7 between 30 and 40; 6 between 40 and 50; 5 between 50 and 60; 4 between 60 and 74. The regions most commonly involved are those most accessible to local infection. The face was affected in 18 cases, the eyelids and the skin surrounding the orbit being a favorite site, ectropion resulting 7 times. The hand or wrist was involved in 11 cases. Other regions affected were the leg, thigh, scrotum, buttock, scalp, back, breast, palm of the hand and sole of the foot. Involvement of the mucous membranes proper has not been reported. The eyelids are a frequent seat of the disease, but the conjunctiva escapes, though the ectropion resulting from the destruction of the lid necessarily causes conjunctivitis, due to exposure.

The subjective sensations of the disease vary greatly. Uncomplicated lesions, as a rule, give rise to but little pain. In some instances the lesions have been very painful, particularly so when the active inflammation has been greatly intensified by secondary infection.

(b) *Description of Lesions.* The disorder begins as a papule or papulo-pustule, which soon becomes covered with a crust. The lesion slowly enlarges peripherally in the form of an indolent, flat, wart-like or crusted papule. In the majority of all cases the lesions had existed a number of months and had attained a diameter of an inch or more before the patient applied for treatment. In a recent case we have had the opportunity of watching a lesion grow from the beginning small papule. As a rule, the disease spreads over contiguous areas from the site of the original papule; but in two or three instances the original lesion has been followed in the course of weeks or months by the appearance in its immediate vicinity of a number of new foci, which have developed and coalesced to form one large area. In about half the cases the original patch of the disease has been followed in the course of weeks or months by one or more new lesions in adjacent or other regions of the body. In some instances the clinical evidence of auto-infection has been very strong.

In lesions that have attained the diameter of half an inch or more, the following characteristics are apparent: The patch is elevated from one-eighth to three-eighths of an inch above the surrounding skin; the surface is covered by irregular papilliform elevations, separated by clefts or fissures of varying depths, giving it a verrucous or cauliflower appearance. In the younger lesions and near the border of the older ones, especially of those which have been kept clean, the papillary projections are fine and the surface is fairly firm, dry and wart-like. Portions of larger lesions, and especially those which have been untreated, are covered by more or less bulky and adherent crusts, on removal of which the papillary elevations are seen to be larger, lobulated, even subdivided, and bathed with a sero-purulent secretion. Some of these crust-covered projections bleed easily. In exceptional instances the area under a crust may present the appearance of an ordinary unhealthy ulcer, with exuberant granulations. In older lesions the papillomatous surface may be replaced in part with a thick, elevated, scar-like formation, pinkish-white in color, ir-

<sup>†</sup> Fig. 33 is from a photomicrograph by Dr. Carl Gramm. Figs. 19 and 24 have been used in the writer's chapter on Diseases of the Skin in the American Text-Book of Pathology, W. B. Saunders & Co. Figs. 3, 17, 22 and 41 have appeared in our Treatise on Diseases of the Skin, Sixth Ed., Lea Bros. & Co.

regular and often corded, but having a smooth, shining surface. (Illustrated in central portions of Figs. 2 and 3.) The base of the active lesion is always soft and more or less infiltrated with sero-pus, which, on slight pressure, oozes out between the papular elevations.

The border of the area is one of the most characteristic features. It slopes more or less abruptly from the elevated roughened surface to the normal skin, from which it is sharply defined. It is smooth, of a dark red or purplish-red color, is from one-eighth to three-eighths of an inch wide, and on close inspection is seen to be set with a large number of very minute abscesses. These abscesses are many of them so small that they are not visible to the naked eye, but can be recognized with a hand-glass magnifying from two to six diameters. Others vary in size up to that of a pinhead. Some are superficial, but many, especially the smaller ones, are deep-seated. When carefully punctured with a fine needle, these abscesses give exit to a small amount of a thick, glairy mucus or muco-pus, the purulent character of the secretion increasing with the size of the pustule. From the smallest abscesses the amount of mucus expressed is sometimes so scanty that it can only be seen with the aid of the hand-glass; yet it is from these minute abscesses that the organisms are best obtained in pure culture. Abscesses of the same sort are seen also in other parts of the growth, and not infrequently on the thick, scar-like tissue described above; but in characteristic development they are best seen on the sloping border. The number of abscesses varies in different cases and in the same case at different times, depending somewhat upon the activity of the process.

*The course of the disease* is irregular but essentially chronic. Usually a number of months elapse before the original patch attains a diameter of an inch or two. It may remain indolent for months or even years, with irregular periods of activity and progress; but, as a rule, extension of the area is slow and continuous. The majority of the areas sooner or later attain the size of a silver dollar or of the palm, and some of them become very much larger. As the disease extends at the periphery, healing frequently occurs in the central portion of the growth. In this manner large areas (in one instance the greater portion of the thigh and leg) may be involved in various stages of the process. Healing sometimes occurs spontaneously. Whether spontaneously or as the result of treatment, the first indication of healing is found in the gradual flattening and disappearance of the papillary projections, partially by absorption, partially by desiccation and exfoliation. At the same time the amount of secretion from the underlying base diminishes, and the whole patch assumes more of an ordinary verrucous appearance. In many instances the papilliform surface is replaced temporarily by the hypertrophic scar-like tissue described above, which in turn gradually disappears and gives place to the characteristic cicatrix, which eventually becomes soft, supple, non-attached, pinkish-white and, on the whole, very inconspicuous, though always sharply outlined from the surrounding skin. As a rule, the resulting deformity is very slight. Involvement of the eyelids is followed by ectropion, and in some instances where destructive agents or scraping operations have been employed, the disappearance of the characteristic lesion is followed by an ordinary indolent ulcer, which heals with a thickened and somewhat deforming scar.

During the healing process, though the miliary abscesses decrease in number, careful search will reveal

them even in scar tissue that has become quite thin and soft. It is consequently not uncommon to see areas that have apparently healed, again become more or less covered with active points or areas of disease. A single patch may thus present nearly all stages of the disorder, tures: the advancing border; new-forming lesions on showing at the same time several of the following fea-old scars; verrucous or cauliflower lesions in various stages of development or disappearance; a base in places dry and firm and in others soft and infiltrated with muco-pus; a scar tissue, in part thick and irregular and in part smooth, soft, supple and non-attached to the in part smooth, soft, supple, and non-attached to the deeper tissues. (Fig. 14 shows a number of scattered lesions which have appeared on an old scar.)

#### ETIOLOGY.

A local infection with the fungus peculiar to each case is the sole recognized cause for the disease. In several instances there has been a history of trauma preceding infection. What other conditions favor the origin and the development of the process have not been determined. Why certain yeasts and mold fungi should be pathogenic, while others are innocuous; how common the pathogenic varieties are in nature, and how they differ from the ordinary varieties, are as yet unsolved problems. It is possible that the difference in virulence between the organisms in blastomycosis and in protozoic disease may be due to the influence of climate, all reported cases of protozoic disease having originated in California.

#### HISTOPATHOLOGY.

In histologic structure the lesions bear considerable resemblance to those of verrucous tuberculosis and carcinoma, yet differ distinctly from both. Sections show a very uneven surface, marked by irregular projections and depressions, the whole covered more or less with irregular masses of debris, consisting of pus, blood, epithelial cells, and various bacteria. The horny layer varies greatly in thickness, being destroyed in places; in others extending in thickened masses deep into the corium between the distorted papillæ.

The striking and characteristic changes occur in the rete, which is the seat of extensive hyperplasia, sending down processes deep into the corium. These processes are exceedingly irregular in size and shape, and send out branches in all directions. They contain the miliary abscesses which are peculiar to this disorder. These abscesses vary in size from a group of half a dozen leucocytes to those which are large enough to be recognized by the unaided eye. They are found in all parts, both superficial and deep, of the hyperplastic epithelium, in places breaking through to the surface above or to the corium below. They contain leucocytes, nuclear fragments, detached epithelial cells, epithelial detritus, red blood corpuscles, the organism peculiar to the disease, and in most cases giant-cells. The epithelial cells surrounding the abscesses are flattened mechanically, but apparently take no active part in the process. The rete everywhere is the seat of more or less edema, polymorphonuclear leucocytes being scattered throughout, both between and within the cells. The rete cells are, as a rule, large and swollen, the prickles being very conspicuous and the intercellular spaces increased. The basal layer of columnar cells is preserved in all the processes. Premature cornification, more or less complete, is seen in scattered individual cells, in groups of cells, and occasionally in isolated epithelial whorls. Single giant-cells, surrounded by a few leucocytes, are occasionally seen in the epithelium at some distance from the corium. (Figs. 18 and 21.)

The corium is the seat of subacute, chronic and occasionally acute inflammatory changes. Miliary abscesses similar to those found in the epithelium are seen also in the corium. The infiltration consists chiefly of leucocytes, young connective tissue cells and plasma cells, and is sometimes very dense,

though in most cases it is more or less diffuse, and, as a rule, can be detected about the blood vessels, where other changes are slight or wanting. The vessels themselves frequently show hyperplasia of all their coats. Mast-cells and giant-cells are frequently seen, but vary in number and character in different cases. Tubercle-like nodules are seen in some instances. In some cases hyalin bodies have been demonstrated in plasma-cells, in giant-cells and in new connective tissue cells. The appendages of the skin apparently take no active part in the process, but, as a rule, disappear early where the infiltration is at all marked. In areas of dense infiltration, the collagen of the corium is completely destroyed.

The organisms characteristic of the disease are found in the miliary abscesses both of the epithelium and of the corium, between the epithelial cells and in the corium, and are always surrounded by more or less evidence of inflammation. (Figs. 21 to 29.) Giant-cells frequently contain one or more of the parasites. The number present varies greatly in different cases. A good section will show from two or three to half a dozen organisms. Other sections will show none, while again a dozen organisms may be recognized in a single field of the microscope. They occur usually in pairs of unequal size, but also singly and in groups. Distinct budding forms can be found readily or after careful search. The organisms show well in sections stained with hematoxylin and eosin, but methylene blue is, on the whole, the most satisfactory stain for showing different parts of the organism. Sections stained for us by Dr. Ormsby with methylene blue and orange tannin, according to Unna's method, have given, on the whole, most satisfactory specimens.

The simplest method of demonstrating the fungus is by placing fresh or hardened unstained sections, teased tissue, or pus between a slide and cover-glass with a drop of water. 10 to 30 per cent. solution of potassium hydrate, or equal parts of liquor potassæ and glycerin. The organisms then appear as double-contoured, highly refractive bodies, in some of which granular contents, vacuoles, or shining, spore-like bodies can be distinguished. (Fig. 34.) A strong solution of potassium hydrate soon disintegrates the tissue cells, but has no influence on the organisms, which consequently show more clearly than in a moist preparation made with water. When well stained, the parasite appears as a round, oval, or slightly irregular body, having a well-defined, double-contoured, homogeneous capsule, which resists the prolonged action of strong alkalis and acids; and a finely or coarsely granular protoplasm, which is usually separated from the capsule by a clear space of varying width. A clear vacuole, varying greatly in size, is seen in some organisms. The diameter of the organism varies, as a rule, from seven to twenty microns, though both larger and smaller forms are occasionally seen. Budding forms in all stages of development have been noted.

#### CULTURES.

The organisms may be obtained from the miliary abscesses and also from the teased tissue and pus. The best method is to clean thoroughly with alcohol or ether a surface showing miliary abscesses. Some of the smallest and deep-seated abscesses are opened with a disinfecting needle, preferably with the aid of a magnifying glass, care being taken to avoid damaging the surrounding tissue. Media inoculated with minute quantities of the tenacious mucus or muco-pus so obtained will show in the majority of instances pure cultures of the organism. In our recent work, more than 50 per cent. of the tubes so inoculated have grown pure cultures of the organisms, while less than 10 per cent. have been contaminated with other bacteria. It is always advisable to inoculate as large a number of media as possible directly from the abscesses, as it sometimes happens that the organism will grow on one or two media and on none of the others. Ordinary media may be employed. Among the best are beer-wort, glycerin and glucose agars. Maltose agar (according to the formula of Sabouraud)

gives a more luxuriant growth with some of the fungi, but on the whole has been less successful in our hands in obtaining cultures from the abscesses than glycerin or glucose agar. Most of the organisms grow best in a medium that is slightly acid.

Cultures made from teased tissue and from the larger and more superficial abscesses are often contaminated with pus-cocci. The fungi have been obtained repeatedly, however, in pure culture on most of the ordinary media from pus abscesses of considerable size, leaving little doubt that the organisms are in themselves pus-producing.

In cultural features the organisms from different cases have varied so widely that it is quite possible they will have to be classed in distinct botanic groups. On the other hand, individual organisms have been shown to vary greatly with the media employed and with other circumstances of culture. As the result of some of our observations, we are inclined to believe that in some cases there may be two varieties of a given species present. This hypothesis would explain some of the phenomena we have observed and would be in keeping with the findings of Hansen, who has demonstrated that the yeasts often occur in nature in groups of allied varieties. Before a rational attempt at classification can be made, the development of each of these organisms from a single cell must be observed and the life-history of each thoroughly worked out. Such study has not been as yet carried out with any one of these organisms.\*

#### APPEARANCE OF THE CULTURES.

For convenience, the following descriptions are limited to appearances on glycerin and glucose agars, as these are stock media in most laboratories and, on the whole, give very satisfactory results for subcultures in practically all organisms, though in some instances primary inoculations have not been so successful as on other media.

The time required for the development of the different organisms in the original cultures varies from 2 to 16 days, the majority showing a growth in from 2 to 8 days. Subcultures appear in from 2 to 5 days. In gross appearances the cultures may show: (a) slightly elevated, white, smooth colonies or irregular areas following the track of the needle; (b) a translucent, gelatinous or yellowish-brown and pasty growth (Fig. 32, tube 17); (c) a roughly granular surface, which may eventually form prominent folds and depressions (Fig. 32, tube 7); (d) a light, white (in older cultures slightly yellow or yellowish-brown) fluffy growth, with short or long aerial hyphæ (Fig. 32, tube 18); or (e) a central white, elevated portion, which may be fluffy or covered with short projections like white hairs, and which is surrounded by a translucent, non-elevated zone (Fig. 35). With very few exceptions, the growth extends more or less into the medium and becomes closely incorporated with it.

Moist preparations from the cultures may show budding organisms; or mycelium that may be fine, homogeneous, and branching, more or less segmented, with or without lateral conidia (Fig. 31), and which may contain few or many highly refractive bodies, varying in size, which are probably spores, though in some instances they may be oil-drops. Mingled with the mycelium may be seen round, oval, or irregular double-contoured bodies, varying greatly in size, and more or less filled with highly refractive globular bodies. (Fig. 30.)

Fig. 32 illustrates very well the great variability of some of the organisms. Nos. 17 and 18 were both inoculated from No. 7 on the same day, and were grown under the same conditions. From No. 17 growths similar to No. 18 have been grown, and from No. 18 growths like No. 17 have been recovered. No. 7

\* A former assistant did considerable work for us during a period of two years on the organisms from these cases, and even published the records; but the work was never carried to a successful termination, and as we have reason to doubt the trustworthiness of some of the findings reported, we are beginning again a systematic study of the organisms from all of our cases.

is a later stage of development of a growth like No. 17. Nos. 7 and 17 are on glycerin agar; No. 18 on glucose agar. Cultures almost identical in appearance with No. 18 have been grown also on glycerin agar. Cover-slip preparations from No. 18 show chiefly fine mycelium, also a few round bodies like those shown in Fig. 30, but smaller. A similar preparation from No. 17 shows a coarser, segmented mycelium containing spore-like bodies, lateral conidia, and more of the round bodies containing globules. Fig. 30 is a moist cover-slip preparation from No. 7. In moist preparations taken from No. 7 two weeks later, the majority of these double-contoured bodies were partially or completely emptied of the spore-like bodies, which appeared in groups outside the capsule, the number in each instance corresponding to the number necessary to fill the capsule. A ruptured capsule or pod with escaping "spores" has been demonstrated several times. These spore-like bodies exhibit Brownian movement both outside the capsule and within the capsules which are partially empty. Hanging drops from Nos. 7, 17, and 18 have practically the same characteristics. No growth is visible for two or three days, when there occurs a rapid growth of fine mycelium. Mingled with it are a large number of the spore-like bodies of various sizes undergoing Brownian movement. Though watched for two weeks, these bodies underwent no further development, and their true nature is not yet determined.

In specimens stained with osmic acid and Sudan iii the capsules, both of the round bodies and of the mycelium, are very faintly tinged; the spore-like bodies are somewhat darker but much less deeply stained than fat globules. With iodine the results are similar to those obtained with osmic acid or Sudan iii, but less pronounced, showing that the bodies are not starch granules.

In hanging-drop and on plate cultures some of the organisms produce varying numbers of oxalate of calcium crystals.

#### ANIMAL EXPERIMENTS.

In a number of cases animals have been inoculated with pure cultures of the organism, resulting in the production of abscesses or granulomatous swellings at the site of inoculation, from which the organism has been again cultivated. Granulomatous nodules have resulted also in the deeper-seated organs, from which the organism has been recovered in pure culture, the animal usually dying from a form of chronic toxemia or marasmus. In the majority of animal inoculations the results have been negative.

#### DIAGNOSIS.

Pathognomonic symptoms are exceedingly rare in the entire list of medical and surgical diseases, and at this time it can not be said definitely that the peculiar miliary abscesses described above are found in this disorder only. It is true, however, that miliary abscesses of the peculiar type described—very minute, the smallest requiring a magnifying glass for their discovery; deep-seated as well as superficial; the contents being a peculiar, tenacious muco-pus—have been observed in all cases examined by us during the past two years; while we have been unable to find just such abscesses in a large number of cases of syphilis, tuberculosis and epithelioma in which we have searched for them. Lesions presenting these abscesses and the characteristic border suggest at once cutaneous blastomycosis.

The readiest means of making the diagnosis is to place the contents of one or more of the abscesses, or a bit of teased tissue, between a slide and cover-glass with a drop of a 20 or 30 per cent. solution of potassium hydrate. If distinct budding organisms are found (Fig. 34), which resist the action of the alkali after the tissue and pus cells have largely disintegrated (a change requiring from ten minutes to one hour), the diagnosis is practically established and needs only verification by obtaining cultures of the organism and by histologic examination of the tissue. Tissue for histologic exam-

ination should not be hardened in formalin, as it produces certain changes in cells that may be confused by the inexperienced with blastomycetes.\*

The disorder could be confounded with syphilis, if ever, in rare cases only, as the symptoms of the two disorders have very little in common. The late manifestations of syphilis are usually circinate in outline, and show in some part of the progressing border the elements—tubercles or ulcers—of which the whole is composed, instead of the smooth, abscess-containing border of blastomycosis. Lesions of syphilis do not persist for years as wart-like elevations without showing in some parts characteristic ulcerations. It is, furthermore, exceedingly rare for such extensive lesions to occur in syphilis and persist for months or years without other evidence or history of the disease being obtainable. Finally, though late lesions of syphilis are seen which refuse to yield to specific treatment, it is certainly to be expected that the majority of cases here presented, if specific, would have disappeared entirely and within a few months under large doses of potassium iodid.

From carcinoma the lesions of blastomycosis cutis are further differentiated by a soft base, by the multiplicity of lesions, by the absence of adenopathy, by spontaneous healing and, finally, by their improvement under the influence of potassium iodid.

Lupus vulgaris in typical development is readily distinguished by its characteristic nodules. Only the hypertrophic and verrucous forms of this disease could be confused with cutaneous blastomycosis. The differential features are practically those considered under verrucous tuberculosis; though the fact that the earliest age at which blastomycosis has appeared is twenty, and that in a majority of cases it first appeared after forty, is of value in the diagnosis.

From verrucous tuberculosis the diagnosis is difficult and depends chiefly on the characteristic border and abscesses of blastomycosis of the skin, on the results of histologic and bacteriologic examination, and on the fact that the morbid condition improves under the influence of the iodine salt. The lesions are, however, larger, more rapid in development, more numerous and more frequently seen on the face than are lesions generally recognized to be tuberculous. The soft, supple scar left by blastomycosis is wholly unlike the deforming scar of tuberculosis. Further, the adenopathy and constitutional symptoms of tuberculosis are wanting. In a doubtful case, tissue should be examined for tubercle-bacilli and guinea-pigs inoculated. In one case (to be reported in detail later) which was observed carefully by us and in which the diagnosis was verified by histologic and cultural findings, the presence of tuberculosis in the early stage was excluded by negative results from repeated examination of tissue for tubercle-bacilli, and by the fact that the lesions disappeared almost entirely under the influence of potassium iodid. A recurrence of the lesions, presenting a somewhat different clinical appearance and showing but slight improvement under large doses of potassium iodid, was followed by a fatal systemic infection with tuberculosis.

\* Tissue for histologic examination should be taken from a progressing border, and should include a portion of normal skin. The incision should be deep enough to include some of the subcutaneous tissue. Small pieces of tissue may be placed at once in absolute, or 95 per cent. alcohol. Larger pieces should be placed for 10 or 12 hours in 70 per cent. alcohol before transferring to stronger alcohol.

Fresh tissue and pus may be preserved for future microscopical examination for several days in a 2 per cent. solution of glycerin, or in a 1:1000 bichlorid solution. For cultures fresh tissue and pus may be kept for a few days in sterile water or in bouillon, but when possible it is much better to inoculate media directly from the abscesses.

Histologically, the miliary abscesses in the rete and in the corium, the extensive leucocytic infiltration, and the characteristic organisms will distinguish cutaneous blastomycosis from tuberculosis, syphilis, or carcinoma of the skin. In blastomycosis the basal columnar layer of the rete is preserved, while in carcinoma it is destroyed.

#### EXCEPTIONS AND ALLIED CONDITIONS.

The disease has been limited strictly to the skin in all instances except in our Case 2 and in that reported by Busse and Buschke. In one other case systemic infection with tuberculosis followed. In the case reported by Curtis, subcutaneous abscesses occurred, in which the blastomycetes were found and cultivated.

In the cases of protozoic dermatitis reported by Rixford and Gilchrist, and others,\* the cutaneous lesions closely resembled those of blastomycosis both clinically and histologically, but the organisms proliferated by sporulation only and not by budding or mycelial growth. Moreover, the disease has been fatal in every case. Our Case 2 and Rixford and Gilchrist's first case of protozoic disease have, however, many features in common. In a case of protozoic infection (in which, however, there were no cutaneous lesions), Ophüls and Moffit cultivated an organism which in many respects resembles closely that found in two of our cases. In fragments of tissue received from Dr. Angle of Lincoln, Neb., budding organisms were very numerous and many of them were filled with spore-like bodies. In several microscopic fields, a ruptured capsule with escaping "spores" could be seen, but to what extent the rupture of the capsule was due to formalin, in which the tissue had been hardened, could not be determined. The sporothrix of Schenck, found in two cases of subcutaneous abscesses, is allied possibly to some of the fungi found in blastomycosis.

#### TREATMENT.

Complete excision of the diseased areas has been successfully practiced in several cases, no recurrence having been reported. Curetting, employed in a number of cases, has not prevented a return of the disease.

Large doses of potassium iodid, first employed by Dr. Bevan in one of our cases, seems to arrest the progress of the disease and produces a marked improvement in the cutaneous lesions. From two to five hundred grains a day have been required in some patients before any effect on the morbid growth was produced. In three of our cases and in two cases reported by others, the disease apparently disappeared under this treatment. In the majority of cases, however, treated with large doses of potassium iodid, healing takes place rapidly over the greater portion of the area involved, but small patches remain, usually of the verrucous border, for indefinite periods; and on the discontinuance of the potassium iodid the disease reappears with as much apparent activity as before. In one of our patients who improved rapidly under the treatment up to a given point, the few remaining verrucous areas and abscesses disappeared after a few exposures to the x-ray, leaving a thickened scar, which at present is slowly being replaced with a typical thin cicatrix.

In all cases, cleansing and antiseptic lotions or dry dressings can be used with advantage.

#### PROGNOSIS.

Out of the thirty-two cases reported, two only have proved fatal. A third patient died of general tuber-

culosis. Complete excision where practiced has terminated the disease. Under the iodine therapy, the condition improves so decidedly that with the aid of the x-ray or other local treatment, the disease should be completely eradicated. The possibility of systemic infection should be remembered.

#### SUMMARY.

Under the term "cutaneous blastomycosis" (or "blastomycetic dermatitis") have been collected a series of cases presenting a clinical picture differing from that of all other recognized dermatoses. The disorder has also a characteristic histopathology. The organisms in tissue have been in every case of the budding variety. In cultures they have appeared as budding or as mycelium-forming fungi, of which there are probably several varieties.

While the disorder occurs independently of all other diseases, it has been followed in at least one instance by tuberculosis. Secondary nos infection of the lesions is common, and there is no reason apparent why secondary infection with tubercle-bacilli or other bacteria should not occur. It is possible also that the fungous disease is capable of implantation upon the lesions of other disorders.

Practically all cases of the disease in which potassium iodid has been employed in large doses have improved decidedly under its administration, but only a small percentage of patients recovered entirely under that treatment alone.

Cutaneous blastomycosis and protozoic dermatitis are undoubtedly closely related disorders, if not varieties of the same process. It is possible, however, that the blastomycetes and other fungi are capable of producing in man a series of disorders of different clinical types.

It is not within the scope of this paper to consider the experimental researches on blastomycetes, protozoa, cancer bodies, cell inclusions, and allied questions, which are at present receiving so much attention in the medical and scientific world. For valuable contributions to these subjects and for full references to the works of previous investigators, the reader is referred to the Second Annual Report of the Cancer Committee to the Surgical Department of Harvard Medical School.<sup>1</sup>

#### NARRATION OF CASES.

CASE I.—F. M., aged 47. Duration of disease two years; \* typical histology and organisms in tissue. (Figs. 25 and 27.) Under long-continued and large doses of potassium iodid, all signs of the disease disappeared excepting a few small verrucous areas on the borders, where miliary abscesses could be detected. The case was reported as greatly improved. The man then spent a year in the country, during which time he neglected treatment. Early in January, 1902, he was again seen in Cook County Hospital, the disease having extended over the greater portion of the arm and forearm, with so much apparent destruction of tissue that it was thought an amputation might be necessary. Three months of treatment with large doses of potassium iodid, and boric-acid dressings have resulted in replacing three-fourths of the diseased area with scar-tissue. On three different occasions, each time on a number of different media, we obtained a mold fungus in pure culture from the miliary abscesses, though similar attempts made while he was under observation two years before were unsuccessful. (We are indebted to Dr. M. M. Portiss for tissue obtained from the patient while in the hospital.)

CASE II.—C. W. T., aged 33. Duration of disease seven years; histologic structure and organisms in the tissue are both typical (Figs. 18, 21, 22, 23 and 24); cultures not obtained. The case was reported by the author as one of cutaneous blasto-

\* For references see report of a case of Dr. D. W. Montgomery, *British Jour. of Dermatol.*, October, 1900.

\* In each case is given the duration of the disease at the time it was reported.

mycosis, in which death occurred from miliary tuberculosis, that being the first postmortem report. In a later report,<sup>3</sup> Dr. Jas. W. Walker, who made the autopsy, showed that the nodules in the lungs contained blastomycetes in abundance and no tubercle-bacilli. This is the only case recorded in which cutaneous blastomycosis of a number of years' duration has been followed by systemic infection. Together with the Busse-Buschke case, in which systemic infection was coincident with the cutaneous lesions, this case might be considered as a connecting link, clinically, between strictly cutaneous blastomycosis on the one side and protozoan disease with systemic infection on the other.

CASE III.<sup>2</sup>—T. R., aged 38. Duration of disease four years; histology and organisms in tissue both characteristic (Figs. 17 and 28); no cultures obtained. After taking large doses of potassium iodid more or less continuously for nearly two years, all traces of the disease except the scar disappeared. The patient is still under observation. There has been no recurrence and no treatment for one year. The ectropion has been overcome by plastic operations by Dr. Dodd.

CASE IV.<sup>2</sup>—F. S. S., aged 33. Duration of the disease two years; histologic structure and organisms in the tissue typical; cultures obtained (Figs. 19, 26, 31, 35, 36, 37, 38, and 39.) Under large doses of potassium iodid, the disease almost entirely disappeared, two or three small areas only remaining. During the past year, though the treatment has been continued the greater portion of the time, very small, flat, verrucous areas persist, and on withdrawal of the medicament for a short period begin to extend to the adjacent skin. During one of these intervals of treatment, a small ridge extended over the upper eyelid. The organism has been obtained repeatedly from the minute abscesses which appear soon after the suspension of treatment.

CASE V.<sup>2</sup>—J. H. C., aged 45. Duration of disease four months; histologic structure in many respects characteristic, but differing somewhat from that of the other cases. The organism (Figs. 40 and 41), a yeast fungus, obtained in pure cultures from the center of the growth, was never demonstrated in the tissues, owing probably to lack of proper technic, as the organism in cultures closely resembled in size and staining qualities infiltration-cells. The condition improved somewhat under potassium iodid. Excision was followed by complete recovery, and no return of the disorder.

CASE VI.<sup>1</sup>—Mrs. A. M., aged 28. Duration of disease two years; histologic structure and organism in tissue both typical; pure cultures of a mold fungus obtained from the abscesses on different occasions. (Figs. 30, 32 and 33.) After six months of continuous treatment with large doses of potassium iodid, no trace of the disease save scar-tissue was left. No recurrence nine months after treatment was suspended. For this case the author is indebted to Dr. W. L. Noble of the Chicago Clinical School.

CASE VII (not previously published).—Miss S. E., aged 21. is in good general health, though she has enlarged glands in the cervical region, and two of her sisters died of tuberculosis. The lesions are located on the right buttock. The first one began as a crusted papule fifteen months prior to the time the photograph was taken; the second appeared a few months later. Their development and their clinical appearances are those described as characteristic of cutaneous blastomycosis. The papillary projections were fine and the lesions comparatively dry and wart-like. But a small amount of secretion could be pressed out between the papillary elevations from the base below. The borders showed characteristic miliary abscesses, from which on a number of occasions and on different media a mold fungus was cultivated.

The histologic structure and organisms in the tissue were practically identical with those found in other cases of cutaneous blastomycosis. The lesions improved rapidly under large doses of potassium iodid, but refused to disappear entirely, a few miliary abscesses appearing promptly on the withdrawal of the drug. A few treatments with the x-ray have caused, in the course of eight weeks, complete disappearance of the abscesses and of the verrucous tissue. There remains yet some hypertrophic scar-tissue, which is apparently slowly disappearing. The case is still under observation.

CASE VIII.<sup>4</sup>—Mrs. M., aged 51. Duration of disease four years; histologic structure and organisms in tissue characteristic (Fig. 29); cultures of what appeared to be a mold fungus were obtained on two different occasions, but subcultures were not successful, and the organism has not, therefore, been studied satisfactorily. This patient has been unable to take potassium iodid in large or continuous doses, and, though the condition has improved somewhat, the lesions have not entirely disappeared. She lives at a distance and is seen only at long intervals.

CASE IX (not previously published).—A. B., aged 54. Duration of disease four months. This case differs clinically from all others that have been recorded, in that the entire lesion presented an appearance very much like that of the hypertrophic scar-like tissue which in some cases temporarily replaces the verrucous patches, and the patient stated that the growth never had been wart-like. The lesion was distinctly elevated, smooth, pinkish-white in color, more or less covered with fine telangiectases, and showed numerous characteristic miliary abscesses on the surface, especially on the border. The base of the tumor was soft and more or less infiltrated with sero-pus. A minute opening (which shows plainly in the photograph, Fig. 11) was made in the surface and the contents shown to be of a gelatinous or myxomatous character. Bits of this tissue and of the tenacious muco-pus from the abscesses were mounted in potassium hydrate and disclosed characteristic budding organisms, such as are shown in Fig. 34. Tissue for histologic examination was not granted by the patient, and but one hurried opportunity was given for obtaining cultures. The media employed, unfortunately, were limited in variety and amount and were not very fresh, and thus no cultures were obtained, all the tubes but one remaining sterile. The man was put on large doses of potassium iodid. At the end of four months he again presented himself for examination. The lesion had entirely disappeared, leaving only a smooth, soft, non-attached scar, a little lighter in color than the normal skin. A communication received from him six months after suspending treatment stated that there had been no recurrence. This patient's individual and family history were excellent. No history or evidence of tuberculosis or syphilis could be obtained.

CASE X (not previously published).—Mrs. D. S., aged 56, gives a remarkably good family and personal history. She has enjoyed unusually good health all her life except for several brief periods of illness. For eight years she had been absolutely well. At present she has no evidence of constitutional disturbance, except that she is extremely nervous and very much worried regarding her condition and unsightly appearance. Early in November, 1901, she experienced a severe mental shock. Three or four weeks later there appeared on the dorsal surface of the left hand, between the first and second metacarpal bones, a small crusted lesion, which gradually spread to its present size (Fig. 13). The lesion was slightly elevated, somewhat verrucous and sharply outlined. Within two weeks after the appearance of the first lesion, similar lesions appeared on the anterior surface of the left leg, a little below the knee; on the left heel; on the anterior surface of the right leg; on the right big toe; on the inner surface of the middle third of the right thigh; and on the left palm, at the base of the thumb. The patient states that during this time there appeared subcutaneous lumps or swellings, varying in size from a bean to a walnut, as follows: Two on the lower half of the left breast as large as walnuts; three smaller ones in the tenth and eleventh intercostal spaces; six or eight similar but smaller lesions on the upper and outer portion of the left thigh. All of these swellings became slightly red on the surface and very sensitive to the touch, but they never became verrucous, crusted, or ulcerated. About two months after their appearance they began to disappear gradually and become less sensitive. Some of these were treated for a time with galvanic electricity.

In the early part of January a lesion appeared on the upper lip, and another on the proximal phalanx of the right index finger. On March 1, while under our observation, a small

papule appeared on the second phalanx of the left index finger. This in a few days became capped with a crust, and in the course of four weeks had developed into a flat papule, a quarter of an inch in diameter, which presented all the characteristics of the disease, including the verrucous surface and the sloping border with miliary abscesses. On two occasions and on six different media, cultures of a mold fungus were obtained from the abscesses of the lesions situated on the lip, on the left hand, on the right index finger, and on the middle third of the right thigh. Tissue taken from the lesion on the anterior surface of the right leg shows the characteristic histologic structure. Typical organisms have been demonstrated in the tissue. Under large doses of potassium iodid, the lesions are rapidly becoming less conspicuous, though none of them has yet entirely disappeared. We are indebted to Dr. P. B. Sauer for the privilege of studying and reporting this case.

This case is unique in that a number of lesions appeared on different parts of the body within a very brief period, a record that would argue against the multiplicity of lesions being due to auto-inoculation; yet the lesions are all situated within easy access of the hands. The subcutaneous lumps or swellings described by the patient had largely disappeared before she came under observation. Such as remain are apparently lymphatic.

CASE XI.—R. B., aged 57. Duration of disease five years; histologic structure and organisms in tissue typical; budding organism cultivated. The disease almost disappeared under large doses of potassium iodid, but recurred on suspension of the drug. As the man had periods of neglecting treatment, the disease was alternately better and worse. About a year after the case was reported, and after a longer period of neglect than usual, the arm was so extensively involved that the man became discouraged and applied to the hospital for amputation. He has since disappeared from observation. The photograph shows a large number of new lesions which appeared over the surface of the old scar soon after cessation of treatment, and after it was supposed the disease was practically eradicated.

CASE XII.—Mrs. J. K., aged 33 (from Dr. Senn's clinic, published here with his permission). Duration of disease two years; histologic structure and organisms in the tissue typical; a mold fungus recovered from the tissue. The lesion (from the face) was excised before the nature of the disease had been demonstrated.

CASE XIII.\*—Mr. S., aged 73. Duration of disease four years; histologic structure and organisms in the tissue characteristic. A mold fungus was cultivated from the abscesses

\* This case was published with our permission by a former assistant, Dr. H. T. Ricketts.<sup>2</sup> This monograph includes very brief reports of Case 12 and of three laboratory cases; also a premature and unauthorized report of the results of much of our work and of our observations for a period covering more than two years. Our published and unpublished records are used freely, though credit for this material is for the most part withheld or given obscurely. A careful reading, for example, does not disclose the fact that of the 68 pages devoted to "new cases," the first 44 are given to five cases previously published,<sup>2</sup> and that 7 pages are devoted to two cases reported by us before the American Dermatological Association, May 30, 1901.<sup>4</sup> In his list of cases, Dr. Ricketts has incorporated Case 2 of our present series, though he never saw the patient and did no work on the case. This case is of special interest, in that it is the only one recorded in which long-continued blastomycosis of the skin has been followed by systemic infection. Repeated reference is made to it in the work (pages 415, 492, 495, 497, 498), always as "Case 5 of this (his) series." No mention is made of its previous publication,<sup>2</sup> though in a foot-note it is stated that "the report is in brief as given by Professor Montgomery." Dr. Ricketts' "Fig. 1c" (his name is affixed to the plate) is from our photomicrograph of a slide prepared by me from this case.<sup>2</sup> The photographs and all the photomicrographs but two are ours. No acknowledgment for them can be found in the work. In two references in the Bibliography to our publications, a claim is made to a share in the original report of "Case 5" above referred to, and to a participation in a review of the literature of blastomycosis by Dr. Hyde.<sup>2</sup>

On pages 516 and 517 are tabulated the more or less completely recorded cultural features of 17 organisms, 7 of them being from "new cases." An examination of the tables and of the descriptions in the text shows that but 3 (2 of which were previously reported) of these 7 organisms have been the subject of careful observation, and that in none of these 3 has an attempt been made to study the life-history of the organism or its development from a single cell. The report on the other 4 organisms is limited to observation of their gross appearances on ordinary media (in tubes only, no plates), and to an examination of a smear or hanging drop. Of one of the organisms subcultures were never obtained. The work is evidently far from complete, yet the writer indulges freely in generalizations and in attempts at classification, including the formulating of a new name, under which the work is published

and from tissue. The lesions improved decidedly under potassium iodid, but not until very large doses were employed. He disappeared from view for six months and then appeared at the Cook County Hospital, where he is now under treatment by Dr. L. B. Baldwin, who reports that the disease has extended over a large part of the face and anterior portions of the scalp.

## A CASE OF SYSTEMIC INFECTION BY A PARACOLON BACILLUS PROBABLY SECONDARY TO TYPHOID FEVER.

WITH THE CLINICAL PICTURE OF ACUTE CHOLECYSTITIS.\*

A. A. BERG, M.D.,

ADJUNCT VISITING SURGEON, MT. SINAI HOSPITAL.

AND

E. LIBMAN, M.D.

ASSISTANT PATHOLOGIST, MT. SINAI HOSPITAL.

NEW YORK CITY.

It would appear from a series of publications which have appeared during the last six years that the members of the group of bacilli intermediate to the typhoid and colon bacilli are destined to become of as much interest in surgical pathology as the typhoid bacillus.

#### MENTION OF PUBLISHED CASES.

It is not our purpose on this occasion to give a complete summary of all the cases of this form of infection that have been described, but it will be of interest to make some note of the cases which have a direct surgical bearing.

If we exclude for the present the scattered cases of cystitis and pyelonephritis in which bacilli of this group have been found in the urine, apparently either primary or secondary, we find that the first striking instance of such an infection of surgical interest is the second of the two cases reported by Achard and Bensaude in a paper entitled "Paratyphoid Infections." Their case was that of a child with acute bronchitis and a moderately-high fever. The bronchitis subsided almost entirely, but the fever gradually rose and remained for almost three weeks. At the end of two weeks there developed a suppurative inflammation of the left sterno-clavicular joint. On incision some pus was evacuated which contained a pure culture of a paracolon organism.

Widal and Nobecourt later published a case, in a man

\* Read in abstract before the Surgical Section of the New York Academy of Medicine.

of 31, of an abscess developing in the neck near the esophagus, from which was obtained a pure culture of an organism which appears to be identical, as far as can be determined from the meager descriptions, with the organism of Achard and Bensaude.

Cushing's case is the best studied thus far. The patient was a man of 27 who, nine months before admission to the Johns Hopkins Hospital, was sick for ten weeks with a fever which was described as being a typical attack of typhoid fever. He had a relapse beginning with an epistaxis. During convalescence a costo-chondral osteomyelitis developed at the level of the fifth rib. Six months later this broke open and discharged pus. In this case also the pus showed an organism which had some of the properties of the typhoid bacillus and some of those of the colon bacillus. The patient's serum gave an agglutination reaction in high dilutions with the organism, but gave no reaction with the typhoid bacillus. On the other hand, sera from cases of typhoid fever which gave a prompt agglutination reaction with the typhoid bacillus gave no reaction when tested with the organism found in the pus. Cushing raises the question whether the original attack was typhoid fever, or whether it was due to the same organism which was found in the osteomyelitic focus. He says that it is unusual to find in post-typhoid lesions organisms of intestinal origin except the typhoid bacilli and the pyogenic skin cocci.

Cushing refers to a case of osteitis described by Blumer, in which the bacterium coli was supposed to have been found in a post-typhoid rib abscess. As Cushing remarks, it is possible that this is another instance of a paracolon infection, because the organism described by Blumer produced alkali in milk and did not ferment lactose. We might mention here that, roughly speaking, the characteristics of the typhoid, colon and intermediate groups are as follows: The typhoid bacillus produces acid in the presence of glucose, no visible gas; it fails to ferment lactose and sucrose. In milk it develops a slight grade of (usually) permanent acidity. The colon bacillus ferments glucose with the production of acid and visible gas, ferments lactose in a similar manner and may or may not ferment sucrose. Milk is usually coagulated in from one to seven days with the development of an acid reaction and the presence of gas bubbles. The bacilli of the intermediary group, or the so-called paracolon bacilli, act like the colon bacillus as regards glucose and like the typhoid bacillus as regards lactose and sucrose. In milk they produce a slight transient acidity followed by a more or less marked alkalinity.

#### THE PRESENT CASE.

The case which we are about to describe is of interest because of its striking resemblance to a condition so frequently referred to surgeons for operative treatment.

The clinical history will be given in full, but the pathologic and bacteriologic findings in abstract only, as it is the purpose of one of the writers to make the latter the subject of a special communication.

#### CLINICAL HISTORY.—A. A. BERG.

Aug. 29, 1901. I was asked by Dr. Hubbard of Boro Park, Brooklyn, to see with him C. I., a clerk, 33 years of age. The patient had been the father of six children, all of whom had died in early infancy, most of them having been "blue babies." His wife had never aborted; he had never had gonorrhea or syphilis; he had no alcohol or tobacco habits.

*Commencement.*—Ten days before the evening upon which the writer saw the patient, the latter had suffered while at business with a sudden attack of nausea, vomiting and feeling

of marked weakness. The vomiting recurred once and the patient felt so sick that he had to stop work and go to his home. Dr. Hubbard saw him at once upon his return home. The patient complained of severe epigastric pain and was moderately prostrated. His temperature was 100 F. and there was considerable abdominal distension. A cathartic was administered and after a free evacuation of the bowels the patient felt much better. The next morning the temperature was a little above 99 F. and the patient was much improved. He stayed in bed, however, for two days, during which time the temperature was not taken on account of the comparative well-being of the patient. After these two days he was up and about but did not feel well enough to go to work. During the following five days he apparently had no fever and did not present himself to his physician.

*Recurrence.*—On the seventh day he was again suddenly seized with intense epigastric pain. The pain was colicky in character and though constantly present was characterized by periods of very marked exacerbation. Although mainly localized in the epigastrium, it occasionally radiated to the back. On this day he vomited twice and had a temperature of 104.2 by mouth. He was again given a cathartic (calomel) which was followed by two copious evacuations, but the patient did not this time experience the same relief as during his first attack. The next morning the temperature was 101.4 by mouth, rising to 103 in the evening. The pain continued with marked severity, and, according to the doctor, was typical in every respect of biliary colic, requiring hypodermic injections of morphin to relieve it. The patient felt very sick; he was slightly jaundiced, but the stools were black in color (from bismuth that had been taken).

#### EXAMINATION.

*The patient*, when seen by me, was evidently much prostrated. His temperature was 104.6 per rectum; his pulse soft and bounding and about 120 to the minute. There was slight subconjunctival icterus; the urine rather scanty and high-colored. The tongue was moist and slightly coated. The lungs practically negative. The apex beat of the heart was in the fifth space outside of the mammillary line. There was a marked heaving of the precordium which extended to the epigastrium. There was a marked systolic murmur over the entire base with its greatest intensity at the second left intercostal space. The second apical sound was accentuated. The heart was dilated, extending  $1\frac{1}{2}$  inches to the right of the sternum and one finger's breadth beyond the left mammillary line. The liver extended from the fourth space in the mammillary line to the free border of the ribs. Its free edge was not palpable; in the epigastrium and adjacent part of the right hypochondrium there was marked pain and tenderness. At this site could be felt a very painful mass the size of a large lemon. There were numerous friction râles over the upper part of the liver. The right rectus muscle was rigid. The spleen appeared to be normal in size. There was no roseola.

*The probable diagnosis* of abscess of the right lobe of the liver pointing in the epigastrium, or of an empyema of the gall bladder was made, and exploratory incision was advised. The patient delayed two days hoping for an improvement in his condition and then entered the Mt. Sinai Hospital. His condition on admission was not materially changed. The temperature had continued high, being 105½ on his entrance to the hospital and his pulse 120. He was very much prostrated, having had high temperatures ever since the onset of the second attack. The physical signs were the same as described above. A Widal reaction proved negative in dilution of 1 to 20. There was no Ehrlich reaction in the urine. The leucocyte count was 15,000.

#### LAPAROTOMY. EXPLORATION OF THE GALL-BLADDER AND BILE DUCT. ASPIRATION OF THE LIVER AND GALL-BLADDER.

*September 1.*—Under chloroform anesthesia, an incision was made through the right rectus sheath extending three inches from the costal margin, the muscle being retracted toward the median line. The peritoneal cavity was opened; there was no fluid in it; the liver came down to the free border. Corresponding to the region where the patient had complained of pain and tenderness was an enlarged Riedel's lobe. The surface of

the liver was for the most part smooth, and over its convexity in the axillary portion was some fresh fibrin. Its color was normal and there were no areas of induration to be palpated. The gall-bladder was moderately distended. Its surface was smooth, its walls apparently not materially thickened. It was found to be impossible to express the contents of the viscous through the bile ducts into the intestine. This feature was very marked. No stones could be palpated within the gall-bladder. Exploration of the ducts showed them to be but slightly thickened and they contained no calculi. The kidney, stomach and pancreas were normal, likewise the appendix. Aspiration of the liver in many directions yielded negative results; aspiration of the gall-bladder yielded thick black bile. The results of the examination will be given later. The puncture in the gall-bladder was closed by Lembert sutures and a small cigarette drain passed down to it. The abdomen was closed by through-and-through sutures.

#### SUBSEQUENT EXAMINATION.

*September 2.*—The patient had rallied well from the operation. His temperature fluctuated between 101 F. and 104; pulse 98 to 120. Epigastric pain continued severe. The abdomen was somewhat distended; the friction râles over the liver were more numerous. The bowels were moved by enema. The urine showed no bile, was acid, contained albumin and hyalin and granular casts.

*September 3.*—The general condition was good. Pulse varied between 118 and 136; the temperature between 102.4 and 104.6. The Widal reaction was negative in dilution of 1 to 20. There was marked subconjunctival and general icterus. The urine contained bile. The bowels were moved by calomel and salines. The urine showed a positive Ehrlich reaction.

*September 4.*—The general condition was not so good. The patient was apathetic and at times irrational. Temperature fluctuated between 102.8 and 105; the pulse rate between 128 and 140. The jaundice was marked. The wound was clean and united, there being only a slight serous discharge through the small drain opening. The liver was apparently not increased in size. Epigastric pain was less. The friction râles over the liver were still marked. There was some slight dullness and exaggeration of breathing at the right apex posteriorly. The systolic murmur at the base of the heart remained the same.

*September 5.*—Apathy continued with mild, quiet delirium. Marked jaundice; general condition poor. Temperature between 102.4 and 106.4; pulse 128 to 132, soft and bounding. Friction râles over the liver very marked; aspiration of the liver in the axillary region over the area of friction râles gave negative results. Cold packs were administered to reduce the temperature, with little effect.

*September 6.*—Widal reaction was negative.

*September 7.*—The patient was more apathetic, delirious and jaundiced. The wound had completely healed. Temperature up to 105. Cold packs continued with somewhat better effects.

*September 8.*—Examination of the blood showed red cells 2,700,000, leucocytes 10,700, hemoglobin 50 per cent. Widal reaction positive in dilution 1 to 200.

*September 9.*—General condition remained the same. Temperature between 101.4 and 105.3; pulse 120 to 140. Marked apathy and jaundice. The patient vomited repeatedly; the vomitus was brownish-black in color, not fecal in odor. Pulse was weaker; face was pinched, and there was Hippocratic facies.

The blood examination showed the following:

Polynuclear neutrophils 84 per cent., small mononuclear 10 per cent., large mononuclear 5 per cent., eosinophils 1 per cent. The total number of leucocytes was 48,000. The urine was acid, containing albumin, hyalin and granular casts and bile. During the night the patient's pulse became more and more feeble, temperature remained high, and towards morning death occurred.

#### REPORT ON THE BACTERIOLOGIC AND THE POSTMORTEM EXAMINATIONS.

E. LIBMAN.

The fluid from the gall-bladder received on September

1 was directly plated and there was found a pure culture of an organism of the intermediate group. To determine whether the presence of organisms in the gall-bladder might not be due to excretion of bacilli from the blood, a blood culture was made on September 4, 11 cubic cm. of blood being used. There was found a very large number of colonies of an organism identical with that which had been isolated from the gall-bladder. On September 9, about ten hours before the patient died, another blood culture was made in the same manner as the previous one and there was found a large number of colonies of the paracolon bacillus, a few colonies of staphylococcus albus and streptococci. A culture from the urine made the same day showed a number of colonies of the paracolon bacillus and a few colonies of the staphylococcus albus.

A short time after the patient died some blood was aspirated from the heart and the culture showed the same organisms as were found on the previous day. The cultures made from the spleen at the time of the autopsy showed colonies of the paracolon bacillus, of the staphylococcus citreus, staphylococcus albus and streptococci. The contents of the ileum were examined with great care for the typhoid bacillus or the paracolon bacillus, but there were found only two varieties of the colon bacillus, bacillus proteus vulgaris, staphylococcus albus and streptococci.

#### AGGLUTINATION REACTIONS.

The serum of the patient was tested daily for the Widal reaction after his entrance into the hospital, but always with a negative result in a dilution of 1 to 20 until September 7, when it became positive in the dilution of 1 to 200. This reaction was instantaneous and complete. On September 8 the reaction was positive in a dilution of 1 to 250. On September 9 in a dilution of 1 to 200, and the serum obtained directly antemortem gave the same results.

As regards the reactions of the patient's blood with the organisms found in the gall-bladder, blood and urine, they were of great interest as the reaction usually resulted in the production of threads instead of clumps, a phenomenon which is seen under certain conditions in making serum reactions, particularly in cases of infection by bacilli in the colon group.

Without going into detail here, it is sufficient to state that the serum of the patient from September 3 on gave a positive reaction with all the bacilli isolated in dilutions varying from 1 to 30 on some days to 1 to 100 on other days.

#### POSTMORTEM EXAMINATION.

The data at our disposal are rather few, particularly because of the great difficulties which stood in our way in attempting to obtain permission for a postmortem examination. We were only allowed to make an examination through the incision.

The heart showed marked hypertrophy of the left ventricle and a lesion of the aortic valve which evidently stood in relation to the traumatism sustained in early childhood, there being a calcareous scar running through the middle of one of the flaps. There was fibrin over the upper lobes of both lungs. The lungs could not be removed for examination. The liver was moderately enlarged; there was a marked perihepatitis; on section it showed the lesions of congestion and parenchymatous degeneration (gross and microscopic examination).

In the gall-bladder there was a small incision. The mucosa was normal. The spleen was moderately enlarged; there was fibrin on the surface. Further exam-

ination showed the presence of acute inflammation, of small areas of necrosis in the pulp, and the presence of enormous clumps of bacilli which were decolorized by the Gram stain. The stomach was markedly dilated; the pancreas showed a moderate grade of interstitial inflammation. The kidneys were normal in size, the capsule was adherent. There was present intense parenchymatous degeneration, thickening of the glomerular capsules and hyalin material in some of the tubules. In the lower ileum there were a number of completely and partially healed ulcers with the remnants of a moderate degree of fibrinous peritonitis on the surface. The mesenteric nodes were moderately enlarged, pale on section. All of the organs were bile stained.

#### EPICRITICAL REMARKS.

This case is a remarkable one from several aspects. That the patient suffered from a systemic infection from a paracolon bacillus is unquestioned, the organism having been found in the blood, in the urine and in the gall-bladder during life. The presence of staphylococci and streptococci in the second blood culture must be ascribed to an agonal invasion. The development of a positive Widal reaction in dilution of 1 to 250 several days after the patient was admitted into the hospital would make it appear very probable that the patient also suffered from an infection by the typhoid bacillus. The presence of a positive reaction after the blood had given absolutely no reaction for several days shows clearly that the reaction can not be ascribed to an attack of typhoid fever at any considerable length of time previous to his last illness. The positive reaction of the typhoid bacillus can also not be ascribed to the paracolon infection because in all the cases of paracolon infection heretofore reported the Widal reaction has been present even in small dilutions, and in all the experimental work in immunizing animals with organisms of the colon group, a reaction with the typhoid bacillus, if it was developed at all, was developed in only small dilutions as compared with the reaction obtained with the infected colon bacillus itself.

Taking the presence of the positive Widal reaction together with the presence in the ileum of the recently healed and healing ulcers, one can not but conclude that the probability in this case is a strong one that the patient suffered from an ambulatory typhoid to which the paracolon infection was secondary. The absence of the typhoid bacillus in all the examinations prevents one from saying positively that such was the case, but on the other hand, indicates that the paracolon infection must have been secondary and had overgrown the typhoid bacilli which had originally caused the infection of the patient.

In my complete paper on the bacteriologic aspect of this case I shall enter into a fuller discussion of these matters and cite some similar but less striking observations in the literature.

#### COMMENTS AS TO THE DIAGNOSIS.

A. A. BERG.

When first seen by the writer the history of the patient's illness, the symptoms and the physical findings suggested the following possible diagnoses:

First, empyema of the gall-bladder with cholangitis; second, abscess of the liver with cholangitis; third, typhoid fever with cholecystitis; fourth, infarction of the liver secondary to an endocarditis. The last condition was considered highly improbable for the following reasons: there were no evidences of a recent endocarditis.

such as disturbed cardiac rhythm, disturbed compensation, pain over the heart, etc., and there were no evidences of emboli in other parts of the body, nor were petechiæ present. The liver was not enlarged as would have been expected in a case of infarction.

As regards the presence of typhoid fever there was no evidence exclusive of the existence of fever, to bear out such a conclusion; there was no roseola and no evident enlargement of the spleen.

At the time I first saw the patient no Widal test or Ehrlich reaction had been made. On the patient's admission to the hospital these were both negative. The subsequent developments in the case, however, and the findings at autopsy, indicate that typhoid fever had probably been present. This would lead us to the assumption that the typhoid fever had been of the ambulatory type and had run the main part of its course before the onset of the marked abdominal symptoms.

The ruling out of these two conditions brought us to the consideration of an abscess of the liver or an empyema of the gall-bladder and no positive conclusion could be arrived at as to which lesion was present. As against abscess was the absence of evidence of any ulceration of the intestine or of the existence of a suppurating focus in some other part; furthermore, in favor of empyema of the gall-bladder was the pain described by the attending physician as typical of biliary colic (still, the mass that was to be felt in the epigastrium did not feel quite like a gall-bladder—its edge was rather too sharp to be taken for this viscus). The slight jaundice might have existed in both conditions. The friction râles over the liver pointed rather to a hepatitis than an empyema of the gall-bladder, though they may have been dependent upon a cholangitis. The hyperleucocytosis pointed to suppuration. It seemed to the writer that the patient was most probably suffering from an empyema of the gall-bladder with cholangitis and perihepatitis, though an abscess of the liver with perihepatitis could not be altogether excluded, and on this basis operation was undertaken.\*

According to the postmortem report, the gall-bladder was normal, but our inability to express the bile from the gall-bladder through the ducts, indicated that an inflammatory swelling of the mucosa of the cystic duct was probably present. This obstruction would explain the biliary colic, and sufficient fibrin was found on the surface of the liver to account for the friction râles. The acute degeneration of the liver and the perihepatitis no doubt account in great measure for the jaundice and the severe local symptoms.

#### CLINICAL MANIFESTATIONS OF THE EARLY STAGES OF CIRRHOSIS OF THE LIVER.\*

FRANK BILLINGS, M.D.

CHICAGO.

Among my ambulatory patients, especially in the office, I have been surprised to find a relatively large number who have applied for relief of various symptoms in whom a palpable, usually tender and enlarged liver could be demonstrated. The symptoms, in the main, were in many patients those of neurasthenia, in others myalgia or a mono-neuritis, or, most frequently, some gastro-intestinal disturbance. In a few cases arthritis was complained of and the affected joints showed evidence of that trouble.

\* Read at the meeting of the Association of Physicians at Washington, D. C., April 30, 1902.

## AN ILLUSTRATIVE CASE.

CASE 1.—B. M. F., aged 54, male, lumber dealer, residence Chicago. The father died of tuberculosis. No other history of inherited disease in the family. Has used alcohol to a very moderate and irregular degree. Smokes moderately.

*Previous Sickness.*—The patient had typhoid fever when 15, from which he made a good recovery and enjoyed perfect health until about 20 years ago. Since that time he has had more or less rheumatism, as he terms it, affecting the muscles, especially of the back; 15 years ago he had pain in the left shoulder and the arm was almost helpless. During the last year he has had pain in the right knee which was at first swollen and painful and later painful when walking or when the leg was extended and flexed upon the thigh. He has been upon a diet almost free from meats for the last eight months and the knee has improved somewhat. He spent a considerable time at Hot Springs, Ark., last spring without relief.

*Examination* showed a well-preserved man. The chest was negative. The liver dulness extended from the sixth rib in the mammary line to below the costal arch, its lower border was palpable, its edge sharp, the consistency increased and tenderness was marked upon firm pressure. The tenderness was felt not only at the point of pressure in the mammary line, but caused also a sharp pain in the epigastrium. This reflection of the pain of a tender liver to the epigastrium when the right lobe was pressed upon below the costal arch was noted in several other cases. The spleen was not palpable. Knee jerks were present. There was distinct crepitus in both knees upon passive flexion and extension, more marked in the right than the left. The right knee was slightly larger than the left and there was slight tenderness over the joint when firm pressure was made, with flexion and extension of the leg. The urine showed sp. gr. 1.022, acid reaction, no albumin, no sugar, no casts, urea 2 per cent.

The diagnosis of chronic interstitial hepatitis with auto-intoxication with resulting arthritis was made.

*Treatment.*—The patient was placed upon a diet free from the red meats and allowed no sweets. A flannel bandage was ordered for each knee and the patient told to exercise daily by walking and to also forcibly extend and flex the knees morning and evening while lying on the back. The medication ordered was 10 gr. doses of the muriate of ammonia after meals, with a sufficient amount of phosphate of soda in hot water on rising to move the bowels daily.

January 30, 1901, the patient was re-examined and found much improved. The liver was still palpable, but less tender and apparently less indurated. There was much less crepitation in the knees. The general management and the medication were continued. On May 11 the patient was again examined, when he complained of some dragging, aching pain in the right hypochondrium with considerable gaseous eructation and epigastric weight after eating. The physical findings were about the same as upon the last examination.

July 11 the patient complained only of itching of the skin which was associated with severe sweating, incident to the hot weather. The liver was less large, less tender and less indurated. He was given 20 gr. doses of the bicarbonate of soda after meals.

October 11 the patient expressed himself as feeling perfectly well. The liver could be felt as a mass descending with inspiration, but its edge could not be felt and it seemed normal in consistency and was not tender. There was no crepitation in the knees and no lameness.

December 3 the patient was seen for the last time. The physical findings were negative as at the time of the last examination. He complained of some fermentative dyspepsia, but was otherwise well. The urine at this time gave a sp. gr. of 1.022, acid reaction, no sugar, no albumin, no casts. He was advised to continue the diet ordered when first seen, to take a good deal of outdoor exercise and to drink water freely as a diluent on rising and three or four hours after each meal.

## REMARKS ON THE CASE.

The case is quoted in full as a not unusual one of a group I shall report, in the history he presented, in the physical findings and in the very favorable results noted.

I wish to say at this point that I do not quote this case as one showing a beginning chronic interstitial hepatitis which was cured by the management noted. It would be very intemperate to say that this case and the others which I shall report were all cases of hepatitis, and that in this and in some others a cure occurred. It is reasonable to suppose that the proliferation of connective tissue which occurs in hepatitis does not resolve and that the improvement in the physical condition of the organ noted was not due to the removal of the inflammatory products, but possibly the relief only of the hyperemia incident to the condition.

I do not make this report with the view of adding anything really new to the treatment of hepatitis, but to mention the many symptoms found in patients with a palpable, tender, often enlarged liver and the co-incident disappearance of many of the symptoms with an apparent restoration of the liver to its normal size, consistency and sensation to touch.

## PALPATION OF THE NORMAL LIVER.

It may be well to note at this point that in health the liver is not easily palpated. A liver of normal consistency and size, with not abnormally thick abdominal walls, may be felt as a mass descending against the palpating hand below the costal arch in the anterior axillary line. One can not feel its edge and would not know by the feel that it was a liver without the knowledge that the liver usually occupies that situation. With an abnormally thick abdominal wall, even this descending mass can not be felt upon the deepest inspiration.

## THE ABDOMINAL LIVER USUALLY PALPABLE.

If one can make out the edge of the liver or can palpate the mass which can be recognized by its contour as the liver, it is not a normal one but is increased in its density and is usually large, although it may be smaller than normal. A palpable liver edge can usually be recognized by the notch in the anterior border which marks the point of separation between the right and left lobes.

A symmetrically enlarged and sharp-edged palpable liver is not necessarily a cirrhotic one: that is due to an increase in the connective tissue element. Passive congestion from a weak right heart, bile stasis from obstruction of the common or hepatic ducts, fatty or amyloid infiltration, may present the same contour and consistence of the liver. The smoothness of the surface of the liver in the early stage of cirrhosis may also resemble the enlargement of the liver due to the conditions named.

Again, one can not state that a cirrhotic liver is in the first stage because it is palpable, indurated, sharp-edged and even tender, for we know that collateral circulation may occur in many of the cases of cirrhosis of the liver, and the venous obstruction and consequent abdominal dropsy, which is so characteristic of the late stage of the disease, may be postponed indefinitely or not appear at all.

Collateral circulation may occur through an enlargement of the deeper veins too, without an enlargement of the branches of the epigastric and of the internal mammary veins which are so often noted enlarged in cirrhosis of the liver with dropsy. The deeper veins which take part in the establishment of collateral circulation are the veins of the suspensory ligament, the diaphragm, the azygos, the esophageal and the gastro-epiploic. If the collateral circulation so established is sufficient, dropsy will not occur and even the superficial veins of the abdomen may remain slightly if at all enlarged. In these cases, therefore, the symptoms will be

chiefly due to the intoxication incident to the cirrhosis of the liver, while the venous obstruction which usually gives rise to dropsy of the peritoneum and to enlargement of the superficial abdominal veins, will remain absent. It is true that hemorrhage from the stomach due to a rupture of the enlarged veins of the stomach wall or of the esophagus may occur as a symptom of the venous obstruction and this, too, in a relatively early period of the disease.

#### STATISTICAL SUMMARY OF THE CASES.

In presenting these cases I have excluded all cases of palpable liver associated with diabetes mellitus, of heart incompetency with chronic venous stasis, of Bright's disease with associated cardiac weakness and venous stasis, of gallstones or other disease obstructing the bile ducts with consequent bile stasis and of all cases of cirrhosis with evidences of portal vein obstruction.

The cases were therefore selected as probable ones of the primary stage of cirrhosis because: first, the liver was palpable, enlarged, usually tender to the touch and had a sharp indurated edge; second, the absence of evidence of other causes of enlargement and induration of the liver; and third, the absence of evidences of portal obstruction. Two cases while under observation developed ascites and were therefore recognized in the early stage.

During the last three years 54 patients have presented themselves with the conditions of liver named above. Of this group all were males. The ages ranged from 30 to 60 years: 11 were from 30 to 40 years, 25 from 40 to 50, 18 from 50 to 60. The ages of the groups correspond to the ages in which atrophic cirrhosis usually occurs.

Three were saloon-keepers and one a brewery agent. The remainder had varied occupations which could have no relation to the disease. One only confessed that he had suffered from syphilis and in none was evidence of syphilis found. Three had suffered from gonorrhea. Twenty-five, or almost one-half the number, confessed to the use of alcoholic beverages, usually whisky in excessive amount; that is, from 6 to 20 drinks a day. Eighteen, or 33 per cent., admitted using alcoholic beverages in small amounts; that is, from 1 to 3 drinks daily—or taking it at irregular intervals in small amounts.

Eleven, or about 20 per cent., denied the use of alcohol at all, and in the case of some of them I know the statement to be true. This is a large proportion to suffer from atrophic cirrhosis not due to alcohol. In these I was unable to trace any other cause for the cirrhosis, as for example, lead poisoning, malaria, previous acute infectious disease, etc.

The majority of the cases sought consultation for some form of disturbance of the digestive tract; 15 had morning nausea and vomiting. This is a form of disturbance common to cirrhosis in all cases and is doubtless due to catarrhal gastritis. The following case illustrates this condition:

#### ILLUSTRATING CATARRHAL GASTRITIS.

CASE 2.—J. M., aged 32, single, no occupation. Presented himself Nov. 20, 1900. Family history good.

*Personal History and Symptoms.*—He had had the acute diseases of childhood, but had always been strong and healthy and recovered quickly from simple acute infections. Had taken exercise. Several years ago he was a hard drinker, using from 3 to 50 drinks a day. He smoked moderately. He had suffered from gonorrhea but never had syphilis. He had acute articular rheumatism in 1896. He sought the consultation for stomach trouble. This began while he was drinking and manifested itself by pain and a sense of heaviness and fulness in

the epigastrium after meals. Occasionally there was morning nausea with gagging and coughing up of slimy mucus. There was much flatulence and the bowels were inclined to be loose. The appetite was usually good. He had less strength, endurance and energy than formerly. He complained of pain in the back, aggravated by stooping, and also a sense of heaviness in the region of the liver. His weight was 10 pounds less than two years before.

*Examination* showed some tenderness in the epigastrium, the edge of the liver palpable below the costal arch, moderately hard and tender. The upper line of dullness began at the sixth rib in the mammary line. The heart and lungs were negative. The spleen was not palpable. The urine: sp. gr. 1.009, pale straw color, acid reaction, no albumin, no sugar, no casts.

*Treatment.*—He was placed upon a diet free from sweets, greases and rich mixtures, and was given hot water a half hour before each meal. Muriate of ammonia in 10 gr. doses was used after meals and phosphate of soda in hot water when necessary as a laxative in the morning. The patient returned on January 14, and said that he was very much improved.

*Recurrence.*—He remained so until recently, when he again drank alcohol to excess. Since that time he has had a return of the old symptoms. The physical condition was practically as upon the first examination, although the liver was somewhat more tender. The same treatment was continued. On May 24, 1901, the patient reappeared and stated that he was in perfect health. The liver edge was still palpable but not tender, but could only be felt at the end of a deep inspiration.

#### REMARKS ON THE CASE.

This case was an undoubted one of alcoholic cirrhosis in the early stage and there can be no question that many of the symptoms of which he complained were toxic in character. The relief was doubtless due to better hygiene and also to the more temperate use of alcoholic beverages.

Gastritis is commonly found also in alcoholic abuse with or without evident cirrhosis of the liver. Congestion of the blood vessels of the stomach from portal stasis from any cause will also cause morning nausea and vomiting.

Twenty-three others of the group suffered from fermentative dyspepsia manifested by epigastric weight, pain and tenderness with eructation of gas, flatulence, etc. The following is a case in point:

#### FERMENTATIVE DYSPEPSIA AS A SYMPTOM.

CASE 3.—A. T., aged 32, married, sewer contractor. Presented himself Nov. 28, 1901.

*History.*—His family history was negative. His health had always been good until the present illness. He had not used tobacco nor alcohol and denied venereal disease. He complained of fulness and weight with belching of gas one to one and a half hours after meals. With this was a sense of weakness and some pain in the epigastrium. Occasional lumbar muscular soreness and headache which lasted for several days at a time. Appetite was poor and the bowels constipated. Had lost 10 pounds in weight during the past year.

*Examination* showed a fairly well-nourished man. Negative findings in the head, neck and lungs. The heart dullness extended from 1½ cm. to the right of the sternum to 2½ cm. to the left of the left nipple; the upper border to the third rib. The apex beat in the fifth interspace 2 cm. outside of the left nipple. The pulmonic second sound accentuated. The liver extended from the sixth interspace in the mammary line to one finger's breadth below the costal arch; its edge was easily palpable and tender and the consistency of the liver was increased. The spleen was not palpable. A single specimen of urine was amber-colored, acid reaction, sp. gr. 1.025, no albumin, no sugar, no casts.

A diagnosis of hepatitis with resulting toxemia was made and patient was placed upon a simple diet without sweets or greases and with plenty of hot water between meals. He was given dram doses of phosphate of soda in hot water on rising in the morning, with the *mistura rhei et sodæ*, 2 dr. after meals.

December 19 the patient again presented himself and expressed a sense of much improvement in health. The digestive disturbance was practically gone; the bowels were still constipated but moved with the phosphate of soda. The liver was found still somewhat enlarged, its edge sharp and tender. The patient has not been seen since that time.

#### GASTROINTESTINAL DISTURBANCES.

As this patient had a mitral insufficiency, the question would naturally arise, was the liver condition due to passive venous stasis? This was probably not true, because there was no sign of broken compensation. The lungs were clear; the spleen was not palpable and the urine was normal.

Thus 38, or about 65 per cent., suffered from disturbance of the digestive tract, chiefly of the stomach: 26 were constipated, requiring the use of medicine to move the bowels: 4 suffered from diarrhea: 3 had alternation diarrhea and constipation; 21 had regular daily bowel movements; only 3 of the group suffered from hemorrhoids.

Hemorrhoids in cirrhosis of the liver is not an uncommon result of obstruction of the portal circulation. It is also claimed by some writers that an associated rectal tenesmus is a not uncommon symptom of the beginning of obstruction of the portal circulation. I was surprised to find that so few of this group suffered from an enlargement of the hemorrhoidal veins.

#### THE COMPLICATION OF MUSCULAR PAIN.

Next to the disturbance of the digestive tract, the most common complaint was of muscular rheumatism, so-called: 12 suffered from lumbago, for which they sought the consultation; 19 from muscular soreness elsewhere in the body, usually, however, combined with lumbago; 2 from sciatica and 2 from musculo-spiral neuritis; 5 had severe headache, usually associated with symptoms of stomach disturbance; 2, arthritis of both knees which had been diagnosed and treated as rheumatism; 8 presented classic symptoms of neurasthenia; that is, lethargy, lessened strength and endurance, nervousness, sleepiness during the day and insomnia at night. The following case illustrates the neurasthenic element:

#### NEURASTHENIA.

CASE 4.—B. C., aged 45, single, lumber dealer, residence in Mississippi. Appeared Jan. 16, 1901.

*History.*—Mother died of cancer of the breast; father of pernicious anemia at 68 years. The patient smoked to excess both cigars and pipe. He had taken from 1 to 6 drinks of whisky a day for several years. Denied venereal disease. Recalled no acute disease during his life. For 6 years had been working 13 to 14 hours a day, taking practically no vacation and no recreation. About one and a half years ago he began to be irritable and nervous and these symptoms became worse with time. For six months he had had pressure at the base of the brain with a sense of heat, numbness and tingling of the skin in places. He had less strength and endurance than formerly and suffered from shortness of breath and palpitation of the heart upon exertion. He was much annoyed by a sense of pressure over the sternum, was often sleepy during the day and suffered from insomnia at night. He was more emotional than formerly. His appetite was usually good, but he suffered from morning nausea and regurgitation of fluids and gas, especially after eating. The bowels were sluggish. He had paid no attention to the selection of foods in his diet and had eaten all sorts of greases and indigestible food. His weight was 136 pounds—average being 155.

*Examination.*—Poorly developed, thin of flesh. Pupils reacted slowly to light and accommodation. Chest negative. The liver edge extended from the sixth rib in the mammary line to one inch below costal arch where it was easily palpable. The edge was sharp and tender and liver density much increased.

The blood showed no plasmodia of malaria. The spleen not palpable. The urine: sp. gr. 1.013, pale, alkaline, no albumin, no sugar. Earthy phosphates were deposited.

*Treatment.*—He was advised to remain north and rest from his business, to take a simple diet, with cold baths in the morning, to stop entirely the use of alcoholic beverages and to diminish the amount of tobacco. A saline was given in hot water on rising in the morning and the *mistura rhei et sodæ* 2 dr. before meals.

January 31 the patient stated he had had two chills in one afternoon since his last visit; but that he had been very nervous at the time and the chill was not followed by any perceptible increase in temperature and no sweat. He slept better, the appetite was improved and the weight increased 2½ pounds. The physical examination presented the same conditions as upon the first examination.

February 14 the patient was still more improved; there was no nausea and the digestion was practically normal. The bowels were still sluggish and the stools not formed.

March 4 the patient presented himself for an acute coryza, but stated that his general condition was very much improved as compared with his condition when he first began treatment. His weight had increased 5 pounds. The liver was still palpable, but much less tender. Treatment was continued.

#### REMARKS ON THE CASE.

This patient's condition was doubtless due to his overwork and especially to his habits of life and the alcoholic misuse. There was doubtless an alcoholic gastritis and there was certainly a hepatitis. The improvement was very marked and steady from the beginning of the improved hygiene. The symptoms were doubtless due to the toxemia incident to the liver and stomach condition, but probably more to the defective liver than to any other cause.

#### OTHER COMPLICATIONS.

Five suffered from chronic pharyngitis, which is not uncommon in alcoholism, and 3 had chronic bronchitis; 13 complained of dragging sensations and soreness in the right hypochondrium, which was aggravated by long standing and increased by palpation of the liver and was usually relieved by lying down. Tenderness of the liver was found on palpation in the 13 named above and also in some of the remaining group who did not suffer from the dragging sensation and tenderness in the right hypochondrium.

#### ASSOCIATED KIDNEY DISEASE.

The urine was normal in 42 cases, that is, it contained no abnormal elements. The specific gravity was not high, as a rule, contrary to the condition usually found when the portal circulation is obstructed. The highest specific gravity was 1.027. In only 2 cases was the specific gravity below 1.010. In all the cases examined the total solids and total urea excreted were within normal limit. A trace only of albumin was found in 12 cases and this was usually associated with the presence of hyalin and in 3 cases, of granular casts.

Chronic interstitial nephritis is not an uncommon association with cirrhosis of the liver of alcoholic origin and evidences of a mild degree of nephritis in 12 of the cases is therefore not surprising.

Glycosuria ranging from a trace to .8 per cent. was found in 4 cases, but there was no polyuria, no hunger or thirst and no wasting. The following is one of the four cases:

#### A CASE WITH GLYCOSURIA.

CASE 5.—J. J. E., aged 58, married, railroad master mechanic. Was seen first Nov. 17, 1900. A brother died at 48 of diabetes. Family history otherwise negative.

*History and Symptoms.*—He has used tobacco very moderately, but none for several years; he used a little alcohol in

the form of beer and wine. He denies venereal disease, had typhoid fever at 22 and pneumonia at 53; has always worked hard and has usually been in good health. Eighteen months ago he noticed that he became more easily tired than usual and had gaseous fermentation with slight constipation. He voided the urine naturally and in not increased amount. His physician found sugar in the urine, but did not state the percentage. He spent the summer of 1899 at Carlsbad and returned very much improved in general health. He now complains of lessened endurance and fatigue which comes with but little physical exertion and his work makes him nervous and fretful. He has a moderate appetite with some gaseous indigestion and no especial thirst. He uses a mixed diet with less starch than he used before the discovery of sugar in the urine, and uses claret or beer once a day with his meals. He uses both tea and coffee. His work requires him to be much out of doors and he is filling his position as a master-mechanic for a railroad, but says that he is not as able to grasp the details of his work as formerly. His present weight is 174 pounds, while 18 months ago it was 190 pounds, his usual weight.

*Examination* shows a well-built, fairly-nourished man. Tongue furred and slightly brownish in color. Pulse 70, regular, tension somewhat increased. Slight sclerosis of the palpable arteries. The heart dullness is one-half inch within the nipple line at the left, the base at the third rib and the right border at the right sternal edge. There is a faint apex systolic murmur made more manifest by a little exercise, which is not transmitted into the axilla. The aortic second sound is somewhat accentuated. The lungs are negative. The liver dullness begins at the sixth rib in the mammary line, the edge is palpable, sharp, firm and tender two inches below the costal margin. The spleen not palpable. The abdomen is otherwise negative. The urine, 1000 c.c. in 16 hours, color yellowish, reaction acid, sp. gr. 1.027, a trace of albumin and .8 per cent. of sugar; 2.4 per cent. of urea, or 24 grms. in 16 hours. Solids for 16 hours 63 grms., of which 8 grms. are sugar.

*Treatment.*—Patient was placed upon a better hygiene in reference to food, the starches and dark meats diminished and the alcoholic beverages taken away and he was given strychnia 1/50 gr. before meals with 10 drops of a 1 per cent. solution of bromid of arsenic after meals.

*December 28* the patient presented himself much improved. The amount of urine in 24 hours was 1800 c.c., reaction acid, sp. gr. 1.022, very slight trace of albumin, 0.8 per cent. of sugar, 1 per cent. of urea, no casts. His weight at this time was 173 pounds, his appetite good, his bowels regular and he made less complaint of neurasthenic symptoms. The liver edge could still be distinctly felt but was not as tender as when first examined.

*May 4, 1901,* there was 1200 c.c. of urine, sp. gr. 1.027, slight trace of albumin, 0.2 per cent. of sugar, 2 per cent. of urea, no casts. He had lost 4 pounds in weight. Otherwise there was nothing new. Treatment, both hygienic and medicinal, continued.

*July 12* the amount of urine was 1500 c.c., color normal, reaction acid, sp. gr. 1.023, a very slight trace of albumin, a trace only of sugar, urea 2.4 per cent., and the sediment contained a few uric acid crystals but no casts. His weight at this time was 170 pounds, with a general improved subjective condition. There was a complaint, however, of pain and tenderness in the region of the right musculo-spiral nerve and slight lumbago. The liver edge could still be felt and slight tenderness remained. He was given 10 gr. doses of muriate of ammonia with the strychnia as before, while the arsenic was discontinued.

*September 14* the amount of urine was 1400 c.c., reaction acid, sp. gr. 1.021, no albumin, sugar very faint trace, urea 1.6 per cent., a few hyalin casts and a few uric acid crystals. The liver area was still slightly increased and the induration and very slight tenderness still remained. The musculo-spiral neuritis was practically well. He complained only of slight gaseous fermentation in the stomach.

*October 19* the urine was 1700 c.c., acid, sp. gr. 1.024, slight trace of albumin, 0.6 per cent. sugar, urea 1.6 per cent., a few granular casts, a few crystals of oxalate of lime and a few sugar spores. The patient felt well, appetite and digestion

good, bowels regular and he presented himself at this time because he desired to have a re-examination. The liver area was still increased in size with some induration, but no tenderness. He had not been so careful with his diet and hence the slight increase in the amount of sugar in the urine. He was again placed upon the bromid of arsenic solution, 10-drop doses after meals, while the general management was continued.

#### ORIGIN OF THE GLYCOSURIA.

This patient would possibly be called a chronic diabetic, but at no time in his history had he a polyuria and the condition of the liver was such that the anatomic diagnosis of cirrhosis was justifiable. Furthermore, he suffered from toxemia, due, doubtless, to the liver condition. This toxemia manifested itself in a neurasthenic state, in myalgia and in a neuritis. I also believe that the glycosuria was due to the liver condition.

It is a well-known fact that sugar may appear in the urine in cirrhosis of the liver and cirrhosis is given as one of the causes of diabetes. It is also true that an induration of the liver with proliferation of connective tissue and degeneration of its cells occurs in diabetes.

Bile, a trace only, was found in 3 cases and was not constant in the 3 as it was not found after the first examination.

Microscopic blood was found in 2 cases and in 1 of these pus was present. The symptoms in both of these patients pointed to urinary calculus.

#### COMPLICATIONS OF THE BLOOD SYSTEM.

The spleen was palpably enlarged in 4 cases. It is known that the spleen is usually palpable in cirrhosis of the liver, due frequently to the venous stasis. It is also true that the spleen may be enlarged from the toxemia due to the cirrhosis or from the infection to which the cirrhosis is due.

Myocarditis occurred in 4, associated with arteriosclerosis of the palpable arteries. There was a mitral systolic murmur in 3; an aortic systolic murmur in 2 and a systolic murmur in the pulmonary area in 2. Inguinal hernia occurred in 3 and there was a palpable right kidney in 4 of the patients.

The existence of arteriosclerosis and cardiac disease in a few of the group had no causative relation to the liver condition I think, because the heart was competent in all of the patients examined.

The presence of calculi in the urinary tract was probably accidental, although it would be consistent to believe that the liver cirrhosis would result in mal-assimilation, possibly leucocytosis with an increase of uric acid and consequently a deposition in the previously bacteriologically infected kidney.

#### MECHANISM OF THE SYMPTOMS.

Cirrhosis of the liver gives rise to symptoms which depend upon two conditions: first, those due to portal obstruction, and second, those due to intoxication in consequence, apparently, of the failure of the diseased liver to modify the products of digestion and the other material absorbed from the digestive tract. The toxemia is further intensified doubtless by the passage of the toxic material from the digestive tract directly to the blood through the collateral circulation. Symptoms of cirrhosis of the liver are therefore usually referred to as obstructive and toxic.

It has appeared to me that the symptoms in the cases presented could be rationally interpreted as due to a toxemia in consequence of the changed anatomy of the liver.

It may be maintained by some that the symptoms

*John A. Wyeth*

noted in these cases occur in patients who have no recognizable change in the liver. Many attribute similar and like symptoms to toxemia from gastrointestinal disorders, with faulty liver action without recognized anatomic defect, or to uric acid in excess from faults of the table, or to defective excretion of waste material through the bowels, skin and kidneys. I shall not attempt to oppose these propositions.

#### CAUSES OF RELIEF OF SYMPTOMS.

As stated above, the cases are presented with a statement of the positive, anatomic, clinical findings and with the subjective symptoms for which the patients sought the consultation.

It may be true that the symptoms were not due to the changed anatomy of the liver, although, as stated above, the coincident improvement in the liver condition with the disappearance of subjective and objective phenomena was striking in some cases.

It is also true that the improvement occurred most markedly in those patients who followed the general management advised, in the way of abstinence from alcoholic drink, in a regulation of the diet to a very simple one, in the adoption of physical exercise or other recreation, and in the use of water as a diluent drink. The improvement was also co-incidental with and in direct ratio, usually, to the improvement in the elimination of waste through the bowels, skin and kidneys.

Admitting this, it does not alter the proposition that the symptoms were due to, or at least aggravated by, changed liver structure. The admitted auto-intoxication association with the indigestion of gastritis or of neurosis of the stomach, or of the toxemia of constipation, etc., would rationally be intensified by a crippled liver.

The fact noted in several cases of improvement in the liver condition with the adopted better hygiene, is important.

In these cases the commonly-associated digestive disturbance was improved or disappeared. Would it be fair, therefore, to believe that the liver condition was due to the abnormal condition of the digestive tract? If so, was the improved liver condition due to the bettered state of the stomach and bowels? If this is granted, one would rationally believe that a beginning liver cirrhosis was checked.

Unfortunately, we do not know the nature of the toxin which occurs in cirrhosis of the liver, nor do we understand what the poison is which occurs in auto-intoxication from indigestion due to disease of the stomach and bowels or to faulty diet, or to constipation, etc. Consequently, our deductions, be they ever so rational, are not truly scientific and are consequently open to controversy and criticism.

#### DIET, HABITS AND HYGIENE.

The treatment followed in the cases reported was an attempt in each case to find the hygienic faults. The diet chosen was made free of heavy meats, of rich mixtures, of greases and sweets and of much fluid with the meals. Alcoholic drink was prohibited. Water was advised as a diluent on rising and three or four hours after each meal. Recreation in the true sense of the word was advised for each. This in the majority consisted of outdoor work or play.

#### MEDICINAL TREATMENT.

The medication followed was indifferent, but the principle followed was to keep the bowels free with the use of a saline in hot water, one-half hour before breakfast. The *mistura Rhei et Sodæ* (U. S. P.) with or without tincture of *nux vomica* in doses of 2 to 4 dr. before or

after meals. Digestive ferments were not used. When hydrochloric acid was deficient in the stomach contents, it was given after meals.

Muriate of ammonia in 10 gr. doses was used in some cases because in the writer's experience its use in cirrhosis of the liver has been coincident with improvement in the liver condition in many cases. Kussmaul many years ago advised the use of ammonium chlorid in the early stage of cirrhosis and I have used it much since that time.

However, in the light of a considerable experience, it is my belief that an improved hygiene, with the use of a saline purgative when it is necessary, will give results quite as good without as with the use of other drugs.

#### HEMOSTASIS OF THE BROAD LIGAMENT.

HENRY P. NEWMAN, A.M., M.D.

Professor of Gynecology, College of Physicians and Surgeons, Chicago; Medical Department of the University of Illinois, and Professor of Gynecology, Chicago Polyclinic.

CHICAGO.

The almost universal employment of the absorbable ligature in surgery of the broad ligament is in itself a

Fig. 1.—The Newman pressure clamp. Model a. Designed for both abdominal and vaginal work. Model b. The more powerful instrument for use in cases where 1000 lbs. or more pressure is required.

confession of the imperfection of our present methods, a protest against the retention of the foreign body in peritoneal wounds, an admission that the less ligature material we use the better. A glance back over the last few decades gives an impressive showing of efforts to do away with it altogether, and while no instrument or appliance has yet been offered upon which we can rely in all circumstances, the *écraseur*, thermocautery, torsion, retention forceps, electrothermic forceps and the angiotribe mark the several stages of progression towards the ideal hemostatic. This should insure: 1. Absolute security against hemorrhage, primary or secondary. 2. Protection against septic contamination. 3. The minimum injury to the parts treated. 4. Absence of foreign bodies from the wound.

By the use of the electrothermic forceps and the angiotribe we can approach very nearly these ideal conditions, but there are some objections which render both impracticable for general use. The former can only be used where there is an electric apparatus at hand, and is thus seldom available except in hospital service.

The latter instrument is made after too many models, is often imperfectly constructed, so that it fails in some

Fig. 2.—Representing the usual methods of hemostasis of the broad ligament: a, en masse ligation, right side; b, individual ligation, left side, with running catgut suture of gaping stump.

vital particular, or it is carelessly used, so that it has not given thus far uniformly satisfactory results.

My own experience with the angiotribe has been most gratifying. In several scores of cases, embracing all varieties of work, I have never had a secondary hemor-

Fig. 3.—The application of the pressure clamp in abdominal excision of the appendages. The same principles are applied in the vaginal operation.

rhage. I have, however, used it with discretion, and in special cases fortified my stumps with an individual catgut ligature, encircling the ovarian or uterine artery in its course along the broad ligament. The advantages of this procedure are apparent when we consider what are the objections to the usual methods of ligation.

In ligation *en masse* there is the danger of loosening and slipping of the ligature from shrinkage of the stump

(Fig. 2 a.); the larger vessels may retract and bleed into the cellular tissue, producing hematoma, of which Tait once tabulated eighty cases; tissue necrosis and the formation of granulating surfaces may give rise to troublesome adhesions; the absorption into the circulation of the waste products of necrosis or saprophytic germs puts an added burden upon nature's resources and retards convalescence; the drawing upon neighboring structures may cause displacement of organs and more or less constant distress or pain; again this method necessitates the employment of large-sized catgut with correspondingly large knots. (Fig. 2 a.)

The objections to individual ligation, on the other hand, are greater danger of secondary hemorrhage; oozing from the stump; the necessity of the running catgut suture to approximate raw surfaces; too much ligature and suture material left in the wound. (Fig. 2 b.)

Of the two methods, individual ligation is the better; but few of us feel safe in tying with catgut the terminal end of a large pulsating vessel and then closing the abdominal wound.

Fig. 4.—Mode of applying the pressure clamp for abdominal hysterectomy. The same principles to be applied in vaginal hysterectomy.

The method which I employ aims to do away with the objections and unite the advantages of the others. The Newman pressure clamp (Fig. 1, models a and b) is applied in the usual manner, if for excision of the appendages or tumors with pedicle, along the roof of the broad ligament (Fig. 3), or directly across the pedicle.

In the former case the bite of the clamp includes the ovarian artery, and by turning the closed instrument half way on the side the artery can readily be seen and encircled by a small catgut ligature just beneath the clamp and on the proximal side of the broad ligament. The main artery is in this way secured, and in the most advantageous way possible, individually and before it emerges from its moorings in the tissues, thus preventing all thought of slipping from the grasp of the ligature. The clamp is removed and the neat, linear stump (Fig. 5) receives no further treatment unless it be septic, as in the case of pus-tubes, when I am accustomed to apply 95 per cent. carbolic acid to the entire cut surface at the site of amputation, or resect the

interstitial portion of the tube, closing the wound in the usual manner with a running catgut.

If by reason of anatomic anomaly or enlargement of the collateral branches a second ligature is necessary, it is applied after or before the removal of the clamp, but always in its course in the substance of the tissue and often in the parchment-like clamped portion.

In hysterectomy both the uterine and ovarian arteries are clamped off and tied in precisely the same manner (Fig. 4).

Used in this way there can be no slipping of the ligature, or contracting and withdrawing of the artery from the stump. The advantages claimed for this method are:

1. Complete and permanent hemostasis, with no pos-

Fig. 5.—The linear stump after the use of the Newman clamp and ligation of the ovarian artery.

sibility of the ligature slipping either off the end of the artery or of the stump.

2. Inability of the artery to contract and draw away from the grasp of the ligature and form hematoma or hematocele.

3. By the combined use of the angiotribe and ligature multiple thrombi are formed, plugging the vessels most securely.

4. There is no puckering up or massing together of broad ligament tissue to draw upon or displace other organs or structures.

5. No strangulated stump tissue remains to slough, granulate and form adhesions.

6. The amount of foreign matter left in the wound is reduced to a minimum.

7. The rapidity of this method and its bloodlessness materially lessen the danger of postoperative shock.

8. Convalescence is eased materially and hastened to a marked degree.

## Clinical Report.

### VALUE OF METHYLENE BLUE IN OPERATING ON FISTULOUS TRACTS.

THEO. C. DAVIS, M.D.

BRIDGETON, N. J.

On June 23, 1901, I was called by Dr. S. to see Miss B., aged 43, she having had during the previous winter an abscess, situated between the right tuberosity of ischium, and anus, opened and twice operated on by a Philadelphia surgeon.

This had refused to heal. On examination, a line of scar tissue was found to extend from the outer side of the anal sphincter almost to the ischial tuberosity; about the center of the scar was a small opening from which oozed pus and the margins of which were undermined and unhealthy. A probe passed upward and outward into the right ischio-rectal fossa, a distance of three and one-fourth inches, but no opening into the rectum could be detected at this examination. The tract was cleaned by hydrogen dioxid and water, equal parts, and afterward with alcohol 50 per cent.; this was continued for about two weeks, tenderness disappeared and the general appearance improved. On using hydrogen dioxid, in full strength with force, a very slight foam discharged from the anus.

Examination by speculum revealed a minute opening about three inches above the anal margin. The patient's general health had improved and we determined on an operation.

Whether by inspiration or unconscious plagiarism, which is so common, I resolved to inject the tract with a solution of methylene blue, thirty grains in an ounce of 50 per cent. alcohol. This was done with considerable force three times during twenty-four hours. The patient having been prepared and an anesthetic administered, the anus was stretched and the small opening in the rectum, stained blue, could be easily seen nearly three inches above the anal margin. A grooved director was passed and the intervening tissue, including the sphincter, divided; separating the edges of the incision, the fistulous tract could be plainly seen stained a deep blue and Y shaped, the prong of the Y, extending into the ischio-rectal fossa, was about one and three-fourths inches; the straight line opening externally was the same length.

The deeply-stained tissue could be easily distinguished, and was removed with a sharp curette and the space carefully cleaned and packed about a moderately soft rubber tube in the rectum, extending beyond the dressings, which were changed as needed.

As so much has been written about the hairpin in surgery, I will state that one spread and bent at an acute angle to keep it from slipping was used inside the rubber tube and prevented obstruction by pressure of packing. The tube allowed passing of flatus and fluids, gave the patient much comfort, and avoided the necessity of changing dressings frequently.

The patient recovered nicely and now has control of stools and flatus. I expected later to make end-to-end suture of the sphincter, but she is satisfied with the result.

The deep staining of the diseased tissue and the ease with which it can be distinguished and completely removed leads me to report this case. I do not think in any other way can we be certain of its complete removal, which accounts for the two previous failures of operation. The injection of methylene blue as described will enable the surgeons to follow any tortuous tract and can be applied to old sinuses of any kind.

18 N. Pearl Street.

---

**The Lisbon Method of Prohibiting Expectoration in Public Vehicles.**—The authorities at Lisbon have issued regulations forbidding spitting on the floor in public vehicles, under penalty of a fine. The point that distinguishes the measure from others of its kind is that the conductor of the vehicle is the responsible party, and the penalty fine is collected from him unless he can produce evidence to prove that he appealed to a policeman and that the latter refused to interfere.

## HISTORY OF THE SECTIONS OF THE AMERICAN MEDICAL ASSOCIATION.

In reviewing the history of the Sections of the Association as given in the Transactions and in THE JOURNAL, there is a certain amount of difficulty from the fact that there are for many years no published official minutes and the data in the general minutes are not uniform or complete. In some cases even the names of officers are not given and in others the Sections were apparently dormant, there being no report from them. In the following pages an attempt has been made to bring together the leading landmarks, the dates of organization, the principal changes that have occurred and the names of those that have served as officers of the different Sections.

For the first twelve years of its existence the American Medical Association held only general meetings; the attendance was not so large, nor the number of articles so numerous as to call for division; it was simply conducted on the usual plan for a medical society or convention. The need of more specialization of its work, however, gradually became apparent, and in 1859

Frank A. Jones, Memphis, Tenn., Chairman, Section on Practice of Medicine.

at the Louisville meeting, Dr. J. B. Lindsley of Tennessee offered the following:

*Resolved*, That a committee of three be appointed by the Chair to inquire into and report upon the propriety of dividing the Association into Sections for the purpose of performing such parts of its scientific labor as may relate to practical branches of medicine and surgery.

This was adopted, and Drs. Lindsley, Brainerd (Ill.) and G. C. Blackman (Ohio) were appointed as the committee.

The next day Dr. Lindsley reported, recommending a division into the following Sections: 1. Anatomy and Physiology. 2. Chemistry and Materia Medica. 3. Practical Medicine and Obstetrics. 4. Surgery. The report was adopted. Later, on the same day, on motion of Dr. H. F. Campbell, a Section on Meteorology, Medical Topography and Epidemic Diseases and one on Medical Jurisprudence and Hygiene were added.

At the New Haven meeting in 1860 reports were called for on the afternoon of the third day. The Sections on Anatomy and Physiology, Practical Medicine and Obstetrics, Surgery and Meteorology, Medical Topography, etc., reported on papers

which were referred to the Committee on Publication. The Section on Chemistry and Materia Medica did not organize.

Up to 1870 the Sections organized at each annual session. In 1869, on motion of Dr. Palmer of Michigan the by-laws were amended so as to make the election of the section chairmen and secretaries by the general meeting on nomination by the Committee on Nominations. They were to be elected at each meeting, and hold office till their successors were chosen at the close of the next year's session. This went into force in 1870 and the officers were thus elected for the ensuing year. In our lists here given the officers are named, from this date on, in the year in which they were chosen.

In 1884 Dr. Foster Pratt offered an amendment to the by-laws empowering Sections to elect their own officers. This was called up the next year at the New Orleans meeting by Dr.

Robert B. Preble, Chicago, Secretary, Section on Practice of Medicine.

Potter and its adoption moved by Dr. Hibberd of Indiana. Dr. Davis (Ill.) moved an amendment that it be laid over for consideration at the next session which on vote was adopted.

At the next meeting, at St. Louis, the change was made and since then, though attempts have been made to restore the old order, the Sections have elected their own officers.

### SECTION OF PRACTICAL MEDICINE AND OBSTETRICS.

The Section of Practical Medicine has had, with certain changes of name and giving off offshoots, a continuous record down to the present time. In the minutes and transactions it is most frequently mentioned as the Section on Practice of Medicine, etc., but we find no record of such an alteration of its designation, and none has been made. One or two attempts have been made to alter it to the Section on Internal Medicine or some other title, but without success, and it still is the Section on Practical Medicine, so far as the records show. The following is its list of chairmen and secretaries:

| YEAR.   | CHAIRMAN.  | SECRETARY. |
|---|--|------------|
| 1860  | Amos Nourse (Me.).....A. K. Gardner (N. Y.).         |            |
| Sessions discontinued on account of Civil War.                                |  |            |
| 1864  | B. Fordyce Barker (N. Y.).....H. R. Storer (Mass.).  |            |
| 1865  | Z. Pitcher (Mich.).....Ellsworth Elliot (N. Y.).     |            |
| 1866  | L. F. Tefft (N. Y.).....W. B. Bibbins (N. Y.).       |            |
| 1867  | M. K. Taylor (Iowa).....E. Hall (N. Y.).             |            |
| 1868  | R. R. McIlvaine (Ohio).....C. M. Finch (Ohio).       |            |
| 1869  | H. F. Askew (Del.).....J. C. Hupp (W. Va.).          |            |
| 1870  | Jos. Kammerer (N. Y.).....J. C. Jackson (Conn.).     |            |
| 1871  | H. R. Storer (Mass.).....J. K. Bartlett (Wis.).      |            |
| 1872  | D. A. O'Donnell (Md.).....B. F. Dawson (N. Y.).      |            |
| Name changed to Section of Practical Medicine, Materia Medica and Physiology. |  |            |
| 1873  | N. S. Davis (Ill.).....Geo. E. Frothingham.          |            |
| 1874  | Austin Flint, Sr. (N. Y.).....J. K. Bartlett (Wis.). |            |
| 1875  | F. G. Smith (Pa.).....B. A. Vaughan (Miss.).         |            |
| 1876  | P. G. Robinson (Mo.).....B. A. Vaughan (Miss.).      |            |
| 1877  | A. L. Loomis (N. Y.).....J. H. Etheridge (Ill.).     |            |
| 1878  | F. F. Rochester (N. Y.).....W. C. Glasgow (Mo.).     |            |
| 1879  | J. S. Lynch (Mo.).....W. C. Glasgow (Mo.).           |            |
| 1880  | Wm. Pepper (Pa.).....T. A. Ashby (Md.).              |            |
| 1881  | J. A. Ochterlony (Ky.).....D. J. Roberts (Tenn.).    |            |

J. H. Carstens, Detroit, Mich., Chairman, Section on Obstetrics and Diseases of Women.

|      |   |
|------|---|
| 1882 | J. H. Hollister (Ill.).....J. G. Lee (Pa.).       |
| 1883 | J. V. Shoemaker (Pa.).....W. C. Will (Conn.).     |
| 1884 | H. D. Didama (N. Y.).....G. M. Garland (Miss.).   |
| 1885 | J. F. Whittaker (Ohio).....B. L. Coleman (Ky.).   |
| 1886 | J. S. Lynch (Md.).....J. B. Marvin (Ky.).         |
| 1887 | A. B. Palmer (Mich.).....N. S. Davis, Jr. (Ill.). |
| 1888 | F. C. Shattuck (Mass.).....G. A. Fackler (Ohio).  |
| 1889 | J. H. Musser (Pa.).....H. McColl (Mich.).         |
| 1890 | V. A. Vaughan (Mich.).....Geo. Dock (Tenn.).      |

"Materia Medica" dropped from name of section on account of formation of Section of Materia Medica.

|      |                                      |
|------|--------------------------------------|
| 1891 | R. T. Edes (Mass.).....J. M. French. |
|------|--------------------------------------|

"Physiology" dropped from name on account of formation of Section of Physiology and Dietetics.

#### SECTION ON PRACTICAL MEDICINE.

|      |  |
|------|--|
| 1892 | C. G. Stockton (N. Y.).....G. W. Webster (Ill.).   |
| 1893 | H. A. Hare (Pa.).....W. H. Washburn (Wis.).        |
| 1894 | E. W. Kellogg (Wis.).....W. E. Quine (Ill.).       |
| 1895 | W. E. Quine (Ill.).....Delancey Rochester (N. Y.). |
| 1896 | J. H. Musser (Pa.).....J. T. Prickley (Iowa).      |
| 1897 | S. A. Fisk (Colo.).....A. A. Jones (N. Y.).        |
| 1898 | F. Billings (Ill.).....C. A. Edson (Colo.).        |
| 1899 | Geo. Dock (Mich.).....T. P. Fitcher (Md.).         |
| 1900 | J. M. Anders (Pa.).....W. Britt Burrs (Ark.).      |
| 1901 | Frank A. Jones (Tenn.).....R. B. Preble (Ill.).    |

#### SECTION ON METEOROLOGY, MEDICAL TOPOGRAPHY AND EPIDEMIC DISEASES.

This Section was organized June 6, 1860, at the New Haven meeting.

| YEAR. | CHAIRMAN.   | SECRETARY. |
|-------|---|------------|
| 1860  | Charles A. Lee (N. Y.).....E. Warner (Md.).   |            |
| 1864  | S. W. Butler (Pa.).....A. N. Bell (N. Y.).  |            |
| 1865  | James Walsh (Conn.).....O. C. Garrett (Mass.).  |            |
| 1866  | B. H. Catlin (Conn.).....N. S. Davis (Ill.).  |            |
| 1867  | B. H. Catlin (Conn.).....N. S. Davis (Ill.).  |            |
| 1868  | B. H. Catlin (Conn.).....N. S. Davis (Ill.).  |            |
| 1869  | Geo. Burr (N. Y.).....N. S. Davis (Ill.).   |            |
| 1870  | Called in this volume (XXI) the Section on Meteorology and Epidemics, or Climatology and Epidemics (both used), showing, however, simply a carelessness in the record. No chairman is mentioned in report of section. Only two papers referred to it. N. S. Davis (Ill.) was secretary. |            |
| 1871  | N. S. Davis.....H. D. Holton (Vt.).   |            |
| 1872  | Geo. L. Sutton.....E. Harris.   |            |
| 1873  | Consolidated with Section on State Medicine and Public Hygiene.   |            |

C. L. Bonifield, Cincinnati, Secretary, Section on Obstetrics and Diseases of Women.

A "Section on Anatomy and Physiology" was one of those proposed in the 12th meeting, when the division into Sections was first suggested, but we find in the minutes no note as to its organization. Nevertheless, in the sixteenth and eighteenth volumes of the Transactions there are minutes of papers being referred to this Section. In the sixteenth volume, p. 48, the permanent secretary reported that no meeting had been held and that it was abolished on motion of Dr. Hibbard of Indiana. The fact is this Section was never organized after the first meeting in New Haven. The papers referred to it were returned to the secretary of the Association and by him to the Transactions at the Boston meeting (1865). The Section was abolished, and anatomy added to the Section on Surgery and Physiology to that on Hygiene, on motion of Dr. Hibbard.

#### SECTION ON SURGERY AND ANATOMY.

The Section on Surgery organized first on June 7, 1860. It has been an active Section at every meeting of the Association since that time, with the exception only of 1863, in which

year the section organizations seem to have been suspended. In 1865 anatomy was added to this Section, making it the "Section on Surgery and Anatomy." The following have been its officers.

| YEAR. | CHAIRMAN.             | SECRETARY.               |
|-------|-----------------------|--------------------------|
| 1860  | Dani Crosby           | Jas. Bryan (Pa.).        |
| 1861  | A. Van Dyke (N. Y.)   | J. Hamburger (N. Y.).    |
| 1865  | H. J. Bigelow (Mass.) | A. B. Hall (Mass.).      |
| 1866  | A. C. Post (N. Y.)    | H. Hobart Page (N. Y.).  |
| 1867  | S. D. Gross (Pa.)     | L. Little (N. Y.).       |
| 1868  | J. L. Atlee (Pa.)     | F. Shrady (N. Y.).       |
| 1869  | Paul F. Eve (Tenn.)   | E. Huesels (Ala.).       |
| 1870  | S. D. Gross (Pa.)     | T. Darby (S. C.).        |
| 1871  | J. W. Russell (Ohio)  | H. Carpenter (Ore.).     |
| 1872  | E. Warren (Md.)       | W. E. Peck (Iowa).       |
| 1873  | S. D. Gross (Pa.)     | A. Garcelon (Me.).       |
| 1874  | E. M. Moore (N. Y.)   | S. Latimer (Md.).        |
| 1875  | A. Garcelon (Me.)     | E. T. Easley (Tex.).     |
| 1876  | D. Hayes Agnew (Pa.)  | Moses Gunn (Ill.).       |
| 1877  | H. H. Smith (Pa.)     | E. T. Easley (Ark.).     |
| 1878  | Moses Gunn (Ill.)     | J. R. Weist (Ind.).      |
| 1879  | W. T. Briggs (Tenn.)  | C. Powell Adams (Minn.). |
| 1880  | Hunter McGuire (Va.)  | Duncan Eve (Tenn.).      |

DeForest Willard, Philadelphia, Chairman, Section on Surgery and Anatomy.

|      |                        |                           |
|------|------------------------|---------------------------|
| 1881 | J. C. Hughes (Iowa)    | W. A. Byrd (Ill.).        |
| 1882 | W. E. Peck (Iowa)      | Paul F. Eve (Tenn.).      |
| 1883 | C. T. Parker (Ill.)    | A. O. Walker (Mich.).     |
| 1884 | Duncan Eve (Tenn.)     | C. B. King (Pa.).         |

#### SECTION ON CHEMISTRY AND MATERIA MEDICA.

This Section organized at the New York meeting (15th) in 1864, with Dr. J. H. Griseom of New York as chairman and Dr.

Corrie of New York, secretary. The following year the minutes make no mention of this Section, but in 1866 we find Dr. W. B. Atkinson of Philadelphia its chairman and Dr. Augustus Mason of Massachusetts acting as its secretary. Beyond the mention of its place of meeting, this Section is not mentioned in the Transactions for 1867. On account of non-attendance of members there was no meeting. In 1868 it was again active, with Dr. J. E. Morgan of Washington City as chairman and Dr. L. J. Deal of Pennsylvania as secretary. There follow two more barren years, 1869 and 1870, as far as any mention of this Section is concerned, but from that time a meeting was held each year.

| YEAR. | CHAIRMAN.           | SECRETARY.           |
|-------|---------------------|----------------------|
| 1871  | D. W. Yandell (Ky.) | H. S. Hurd (Ill.).   |
| 1872  | J. S. Crane (N. J.) | Eph. Cutter (N. Y.). |
| 1873  | R. E. Rogers (Pa.)  |                      |

Under the rearrangement of the Sections made in 1873, the Section on Chemistry, Materia Medica and Therapeutics ended its history, and was thereafter continued, if it can be so said,

James B. Bullitt, Louisville, Ky., Secretary, Section on Surgery and Anatomy.

in the Section on Medical Jurisprudence, Chemistry and Psychology.

#### SECTION ON MEDICAL JURISPRUDENCE AND HYGIENE.

This Section was provided for on motion of Dr. H. F. Campbell at the 12th meeting of the Association at Louisville in 1859, but we find no record of its organization until 1865, though the minutes report papers referred to it before that date. The officers for 1865 were Dr. J. F. Hibbard of Indiana, chairman, and Dr. Robert Burns of Pennsylvania, secretary. With the abolition of the Section on Anatomy and Physiology, the Section was made the Section on Medical Jurisprudence, Physiology and Hygiene. Its officers so far as we can ascertain from the minutes for the subsequent years were as follows:

| YEAR. | CHAIRMAN.       | SECRETARY.          |
|-------|-----------------|---------------------|
| 1866  | W. Jewell (Pa.) | A. N. Bell (N. Y.). |
| 1867  | Record wanting  |                     |
| 1868  | Record wanting  |                     |

| YEAR. | CHAIRMAN.                 | SECRETARY.             |
|-------|---------------------------|------------------------|
| 1869  | J. F. Hibberd (Ind.)..... | J. K. Bartlett (Wis.). |
| 1870  | F. H. Getchell (Pa.)..... | Benj. Blackford (Va.). |
| 1871  | Record wanting.....       |                        |
| 1872  | S. C. Busey (D. C.).....  | S. L. Howard (Md.).    |

In the reorganization of 1873 it was consolidated with the Sections on Chemis-try, Materia Medica, etc., and on Psychology into the Section on Medical Jurisprudence, Chemistry and Psychology.

#### SECTION ON PSYCHOLOGY.

This Section was provided for at the same time as that on Medical Jurisprudence and Hygiene. It apparently did not have a very vigorous life; the medical superintendents of asylums of the country had their own association and did not co-operate as was the hope when the Section was formed. This is apparent in several entries in the general minutes. The officers of the Section so far as can be ascertained were:

Arthur R. Reynolds, Chicago, Chairman, Section Hygiene and Sanitary Science.

| YEAR. | CHAIRMAN.                 | SECRETARY.            |
|-------|---------------------------|-----------------------|
| 1866  | C. A. Walker (Mass.)..... |                       |
| 1867  | W. A. Lee (N. Y.).....    | H. R. Storer (Mass.). |
| 1868  | D. F. Condie (Pa.).....   | C. A. Lee (N. Y.).    |
| 1869  | .....                     | .....                 |
| 1870  | J. P. Gray (N. Y.).....   | A. Hartmann (Md.).    |
| 1871  | .....                     | .....                 |
| 1872  | Isaac Ray (R. I.).....    | J. Curwen (Pa.).      |

In 1873 this Section was left out in the rearrangement, or rather, we may perhaps say, was consolidated with the Section on Medical Jurisprudence and Chemistry.

In 1870 it was recognized that the Sections were not doing uniformly their best work, that two or three of them engrossed the attention of members and that the others were comparatively neglected. A special committee was therefore appointed to devise a plan for a better arrangement of the Sections and a more rigid examination of papers submitted for publication. This committee, of which Dr. E. Lloyd Howard of Maryland was chairman, reported at the St. Louis meeting (24th) in 1873 and

proposed a reduction in the number of Sections from six to five, which should be as follows:

1. Practical Medicine, Materia Medica and Physiology.
2. Obstetrics and Diseases of Women and Children.
3. Surgery and Anatomy.
4. Medical Jurisprudence, Chemistry and Psychology.
5. State Medicine and Public Hygiene.

The Section on State Medicine and Public Hygiene was to be composed of one member from each state, representing as far as practicable the state boards of health, and its officers were to be designated by the committee on nomination.

This report and the resolution making the changes suggested were accepted at this meeting and the Sections rearranged accordingly. It will be seen that we have thus one Section omitted—that on Medical Topography, etc.—two altered and consolidated and two new ones, those on Obstet-

H. M. Bracken, Minneapolis, Minn., Secretary, Section on Hygiene and Sanitary Science.

rics and State Medicine, and one unchanged. Of the new ones, the Section on Obstetrics has given off the Section on Diseases of Children in 1880, but it is otherwise unchanged at the present time. Its list of officials so far as ascertained is as follows:

#### SECTION ON OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

| YEAR. | CHAIRMAN.                | SECRETARY.              |
|-------|--------------------------|-------------------------|
| 1873  | Theo. Parvin (Ind.)..... | M. A. Pallen (Mo.).     |
| 1874  | W. H. Byford (Ill.)..... | S. C. Busey (D. C.).    |
| 1875  | S. C. Busey (D. C.)..... | R. Battey (Ga.).        |
| 1876  | J. P. White (N. Y.)..... | R. Battey (Ga.).        |
| 1877  | E. W. Jenks (Mich.)..... | H. O. Marcy (Mass.).    |
| 1878  | E. S. Lewis (La.).....   | J. R. Chadwick (Mass.). |
| 1879  | A. H. Smith (Pa.).....   | R. Battey (Ga.).        |

#### SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

|      |                             |                        |
|------|-----------------------------|------------------------|
| 1880 | J. R. Chadwick (Mass.)..... | J. T. Johnson (D. C.). |
| 1881 | H. O. Marcy (Mass.).....    | C. V. Mottram (Kan.).  |
| 1882 | J. R. Bartlett (Wis.).....  | G. A. Moses (Mo.).     |
| 1883 | T. A. Reamy (Ohio).....     | J. T. Jolks (Ark.).    |
| 1884 | R. S. Sutton (Pa.).....     | J. T. Jolks (Ark.).    |
| 1885 | S. C. Gordon (Me.).....     | J. Paine (Tex.).       |
| 1886 | F. M. Johnson (Mo.).....    | W. W. Jaggard (Ill.).  |

| YEAR. | CHAIRMAN.                 | SECRETARY.              |
|-------|---------------------------|-------------------------|
| 1887  | E. Van De Warker (N. Y.). | E. W. Cushing (Mass.).  |
| 1888  | W. H. Wathen (Ky.).       | A. B. Carpenter (Ohio). |
| 1889  | W. W. Potter (N. Y.).     | J. Hoffman (Pa.).       |
| 1890  | C. A. L. Reed (Ohio).     | H. A. Kelly (Md.).      |
| 1891  | E. E. Montgomery (Pa.).   | F. H. Martin (Ill.).    |
| 1892  | J. M. Duff (Pa.).         |                         |
| 1893  | J. Eastman (Ind.).        | G. I. McKelway (Pa.).   |
| 1894  | F. H. Martin (Ill.).      | O. Werder (Ohio).       |
| 1895  | J. T. Johnson (D. C.).    | R. Peterson (Mich.).    |
| 1896  | Milo B. Ward (Kan.).      | G. H. Noble (Ga.).      |
| 1897  | Jos. Price (Pa.).         | C. Lester Hall (Mo.).   |
| 1898  | A. H. Cordler (Mo.).      | W. A. Haggard (Tenn.).  |
| 1899  | W. E. B. Davis (Ala.).    | F. F. Lawrence (Ohio).  |
| 1900  | H. P. Newman (Ill.).      | C. L. Bonifield (Ohio). |
| 1901  | J. H. Carstens (Mich.).   | C. L. Bonifield (Ohio). |

#### SECTION ON MEDICAL JURISPRUDENCE, CHEMISTRY AND PSYCHOLOGY.

This Section, formed in the reorganization of 1873, was really a consolidation of the Sections on Chemistry, Psychology and Medical Jurisprudence, the latter dividing also with the new Section on State Medicine and Hygiene. Under its new

Frank Allport, Chicago, Chairman, Section on Ophthalmology.

style the Section continued to 1879, under the following officers:

| YEAR. | CHAIRMAN.              | SECRETARY.               |
|-------|------------------------|--------------------------|
| 1873  | A. N. Tilley (S. C.).  | E. L. Howard (Md.).      |
| 1874  | Jerome Cochran (Ala.). | G. A. Moses (Mo.).       |
| 1875  | E. L. Howard (Md.).    | E. A. Hildreth (W. Va.). |
| 1876  | Eug. Grissom (N. C.).  | E. A. Hildreth (W. Va.). |
| 1877  | W. Kempster (Wis.).    | E. A. Hildreth (W. Va.). |
| 1878  | W. M. Compton (Miss.). | L. M. Eastman (Md.).     |

In 1879 it again changed, becoming merged with the Section on State Medicine. Medical Jurisprudence does not reappear as a section subject till 1887.

#### SECTION ON STATE MEDICINE AND PUBLIC HYGIENE.

This Section was organized in 1873, as already said, with representatives from each state, preferably representing boards of health and hence a quasi official organization, continued under that style and title till 1879, with the following officers:

| YEAR. | CHAIRMAN.                  | SECRETARY.            |
|-------|----------------------------|-----------------------|
| 1873  | A. N. Bell (N. Y.).        | A. B. Stuart (Minn.). |
| 1874  | H. I. Bowditch (Mass.).    | H. B. Baker (Mich.).  |
| 1875  | R. C. Kedzle (Mich.).      | E. M. Hunt (N. Y.).   |
| 1876  | E. M. Hunt (N. Y.).        | D. R. Wallace (Tex.). |
| 1877  | J. L. Cabell (Va.).        | J. T. Reeves (Wis.).  |
| 1878  | J. S. Billings (U. S. A.). | J. T. Reeves (Wis.).  |

At the Atlanta meeting (30th) in 1879 it was on motion of Dr. A. N. Bell consolidated with the Section on Chemistry and Psychology, under the title of the Section on State Medicine, Public Hygiene, Chemistry and Psychology, with Dr. J. F. Hibberd of Indiana as chairman and Dr. J. F. Wood of North Carolina, secretary. The following year its name was changed to the Section on State Medicine. The method of nomination of members of this section was retained, according to the minutes, till 1891 when, by an amendment offered by Dr. N. S. Davis, it selected its own officers. In 1900 its name was changed to Section on Hygiene and Sanitary Science. Its roster of officers from the consolidation to the present is as follows:

C. A. Veasey, Philadelphia, Secretary, Section on Ophthalmology.

#### SECTION ON STATE MEDICINE, PUBLIC HYGIENE, CHEMISTRY AND PSYCHOLOGY.

| YEAR. | CHAIRMAN.                   | SECRETARY.                     |
|-------|-----------------------------|--------------------------------|
| 1879  | J. F. Hibberd (Ind.).       | J. F. Wood (N. C.).            |
| 1880  | J. T. Reeve (Wis.).         | R. G. Jennings (Ark.).         |
| 1881  | A. L. Gibson (U. S. N.).    | J. H. Sears (Tex.).            |
| 1882  | Foster Pratt (Mich.).       | Thos. L. Neal (Ohio).          |
| 1883  | D. J. Roberts (Tenn.).      | C. W. Franzoni (D. C.).        |
| 1884  | E. W. Schaeffer (Mo.).      | J. N. McCormack (Ky.).         |
| 1885  | J. H. Rauch (Ill.).         | F. E. Daniell (Tex.).          |
| 1886  | G. H. Rohe (Md.).           | W. Wyman (U. S. M. H.).        |
| 1887  | H. B. Baker (Mich.).        | S. T. Armstrong (Tenn.).       |
| 1888  | J. B. Lindsay (Tenn.).      | S. T. Armstrong (U. S. M. H.). |
| 1889  | J. B. Hamilton (D. C.).     | F. S. Rascum (Utah).           |
| 1890  | J. D. Plunkett (Tenn.).     | F. S. Rascum (Utah).           |
| 1891  | Benj. Lee (Pa.).            | L. F. Flick (Pa.).             |
| 1892  | C. A. Lindsley (Conn.).     | S. P. Duffield (Mich.).        |
| 1893  | G. W. Stoner (U. S. M. H.). | C. H. Shephard (N. Y.).        |
| 1894  | L. H. Montgomery (Ill.).    | C. H. Shephard (N. Y.).        |
| 1895  | C. H. Shephard (N. Y.).     | Elmer Lee (Ill.).              |
| 1896  | Elmer Lee (Ill.).           | L. F. Bishop (N. J.).          |
| 1897  | J. N. Quimby (N. J.).       | A. R. Reynolds (Ill.).         |
| 1898  | A. R. Reynolds (Ill.).      | W. P. Munn (Col.).             |
| 1899  | W. C. Woodward (D. C.).     | Amand Ravold (Mo.).            |

## SECTION ON HYGIENE AND SANITARY SCIENCE.

| YEAR. | CHAIRMAN.                 | SECRETARY.             |
|-------|---------------------------|------------------------|
| 1900  | Ernest Wende (N. Y.)....  | J. N. Hurty (Ind.).    |
| 1901  | A. R. Reynolds (Ill.).... | H. M. Bracken (Minn.). |

## SECTION ON OPHTHALMOLOGY, OTOTOLOGY AND LARYNGOLOGY.

In 1878, this Section was constituted, and the following year was in working order. It continued as such till the year 1888, when the Section on Laryngology and Otology was separated; it has since been known as simply the Section on Ophthalmology. The following is its list of officers:

| YEAR. | CHAIRMAN.                      | SECRETARY.             |
|-------|--------------------------------|------------------------|
| 1879  | B. A. Pope (Mo.).....          | Eug. Smith (Mich.).    |
| 1880  | D. S. Reynolds (Ky.).....      | S. M. Barrett (D. C.). |
| 1881  | D. B. St. John Roosa (N. Y.).. | J. Solis Cohen (Pa.).  |
| 1882  | A. W. Calhoun (Ga.).....       | Carl Seiler (Pa.).     |
| 1883  | J. F. Chisholm (Md.).....      | J. L. Thompson (Ind.). |
| 1884  | J. A. White (Va.).....         | Eng. Smith (Mich.).    |
| 1885  | Eugene Smith (Mich.).....      | J. F. Fulton (Minn.).  |
| 1886  | X. C. Scott (Ohio).....        | J. H. Thompson (Md.).  |
| 1887  | F. C. Hotz (Ill.).....         |                        |
| 1888  | G. E. Frothingham (Mich.)..    | G. C. Savage (Tenn.).  |

## SECTION ON OPHTHALMOLOGY.

|      |                         |                       |
|------|-------------------------|-----------------------|
| 1889 | S. C. Ayres (Ohio)..... | E. J. Gardner (Ill.). |
| 1890 | L. Connor (Mich.).....  | T. E. Murrell (Ark.). |

H. M. McClanahan, Omaha, Neb., Chairman, Section on Diseases of Children.

|      |                             |                            |
|------|-----------------------------|----------------------------|
| 1891 | J. Thompson (Ind.).....     | G. E. de Schweinitz (Pa.). |
| 1892 | S. D. Risley (Pa.).....     | H. H. Gradle (Ill.).       |
| 1893 | A. R. Baker (Ohio).....     | L. H. Taylor (Pa.).        |
| 1894 | Edw. Jackson (Pa.).....     | H. V. Würdemann (Wis.).    |
| 1895 | Lucien Howe (N. Y.).....    | Frank Allport (Ill.).      |
| 1896 | G. E. de Schweinitz (Pa.).. | H. M. Starkey (Ill.).      |
| 1897 | H. Gifford (Neb.).....      | R. Randolph (Md.).         |
| 1898 | Casey A. Wood (Ill.).....   | A. H. Williams (Mass.).    |
| 1899 | H. V. Würdemann (Wis.)..    | C. F. Clark (Ohio).        |
| 1900 | J. A. Lippincott (Pa.)..... | E. C. Ellet (Tenn.).       |
| 1901 | F. Allport (Ill.).....      | C. A. Veazy (Pa.).         |

## SECTION ON DISEASES OF CHILDREN.

At the New York meeting of the Association (31st) in 1880, on motion of Dr. M. A. Pallen, a temporary Section on Diseases of Children was added to those already existing, and was later, by request of its members, made a permanent one by a unanimous adoption of an amendment to the by-laws proposed by Drs. S. C. Busey. It has continued, without change in its

name, an active Section down to the present. The following is its list of officers:

## TEMPORARY ORGANIZATION.

| YEAR. | CHAIRMAN.  | SECRETARY.                |
|-------|--|---------------------------|
|       | S. C. Busey (D. C.).....   | Frank Woodbury (Pa.).     |
| 1880  | A. Jacobi (N. Y.).....   | W. H. Bradford (Mass.).   |
| 1881  | S. C. Busey (D. C.).....   | W. Lee (Md.).             |
|       | (Wm. Lee, in absence of Dr. Busey, chairman, at meeting in 1882, and E. C. Miller (Iowa) secretary.) |                           |
| 1882  | R. F. Blount (Ind.).....   | J. H. Sears (Tex.).       |
|       | (C. W. Earle (Ill.) elected in his (E. L. Bothby (Wis.) elected in absence.) his absence.)           |                           |
| 1883  | Wm. Lee (Md.).....   | W. R. Tipton (N. M.).     |
| 1884  | J. H. Pope (Tex.).....   | S. S. Adams (D. C.).      |
| 1885  | W. D. Haggard (Tenn.).....   | W. B. Lawrence (Ark.).    |
| 1886  | Delaskie Miller (Ill.).....  | W. B. Lawrence (Ark.).    |
| 1887  | F. E. Waxham (Ill.).....   | W. B. Lawrence (Ark.).    |
| 1888  | J. A. Larrabee (Ky.).....  | C. J. Jennings (Mich.).   |
| 1889  | I. N. Love (Mo.).....  | E. F. Brush (N. Y.).      |
| 1890  | W. P. Watson (N. J.).....  | H. A. Hare (Pa.).         |
| 1891  | E. F. Brush (N. Y.).....   | B. A. Waddington (N. J.). |

Frank X. Walls, Chicago, Secretary, Section on Diseases of Children.

|      |                                |                         |
|------|--------------------------------|-------------------------|
| 1892 | C. G. Jennings (Mich.)...      | F. S. Parsons (Mass.).  |
| 1893 | W. S. Christopher (Ill.)...    | F. A. Churchill (Ill.). |
| 1894 | E. H. Small (Pa.).....         | G. W. McNeill (Pa.).    |
| 1895 | A. C. Cotton (Ill.).....       | J. A. Work (Ind.).      |
| 1896 | J. A. Larrabee (Ky.).....      | H. E. Tuley (Ky.).      |
| 1897 | J. P. Crozier Griffith (Pa.).. | E. Rosenthal (Pa.).     |
| 1898 | H. E. Tuley (Ky.).....         | J. L. Booker (Mo.).     |
| 1899 | E. Rosenthal (Pa.).....        | L. Fischer (N. Y.).     |
| 1900 | S. W. Kelly (Ohio).....        | W. E. Darnall (N. J.).  |
| 1901 | H. M. McClanahan (Neb.)..      | F. X. Walls (Ill.).     |

We have been aided in this sketch by the address of the chairman, Dr. Larrabee, given in 1897.

## SECTION ON DENTISTRY.

As regards the Dental Section, the following is contributed by Dr. N. S. Davis: "A small number of dentists became members of the American Medical Association and participated in the proceedings from an early period in its history. But they gained this membership not as dentists but as graduated M.D's. and members of the regular medical societies where they lived.

Such was the case with the late Dr. W. W. Allport and E. S. Talbot of Chicago, Dr. D. H. Goodwillie of New York, and John S. Marshall of Syracuse.

"Dentistry was first formally recognized as a legitimate part of the general field of medicine and surgery and provision made for admitting dentists and the organization of a Section on Dentistry which name was changed the next year to Dental and Oral Surgery at the meeting of the American Medical Association in Richmond, Va., 1881. The movement was suggested by Drs. Allport, Talbot and Marshall, who thought a good section could be sustained. The necessary amendment to the by-laws of the Association was moved by Dr. S. D. Gross and seconded by both Lewis A. Sayre and myself and were adopted with little or no opposition. The new section was organized at the next annual meeting of the Association, which was at St. Paul in 1882 and has been fairly well sustained every year since."

This Section, as will be seen by the following list of officers, is unique among the Sections in having almost a permanent

A. H. Peck, Chicago, Chairman, Section on Stomatology. secretary, Dr. E. S. Talbot, to whose interest and energy it must owe much of its success. Since 1898 it has been known as the Section on Stomatology.

#### SECTION ON DENTISTRY.

| YEAR.                               | CHAIRMAN.                | SECRETARY.             |
|-------------------------------------|--------------------------|------------------------|

#### SECTION ON STOMATOLOGY.

| YEAR. | CHAIRMAN.              | SECRETARY.           |
|-------|------------------------|----------------------|
| 1898  | G. V. I. Brown (Minn.) | E. S. Talbot (Ill.). |
| 1899  | M. H. Fletcher (Ohio)  | E. S. Talbot (Ill.). |
| 1900  | R. R. Andrews (Mass.)  | E. S. Talbot (Ill.). |
| 1901  | A. H. Peck (Ill.)      | E. S. Talbot (Ill.). |

#### SECTION ON MEDICAL JURISPRUDENCE.

In the President's address at the St. Louis (37th) annual meeting of the Association the suggestion of two new sections, one on Medical Jurisprudence and one on Dermatology and Syphilis, was made. A committee was appointed (Drs. J. H. Murphy, A. L. Gihon, and A. Garcelon) to consider the President's recommendations and reported in favor of the same. The Section on Medical Jurisprudence had Neurology added to its title by motion of Dr. Callender of Tennessee in 1891, and in 1900 its name was still further changed to the Section on Nervous and Mental Diseases. Unlike the old Section on Psychology, of which it is the legitimate successor, it has been

E. S. Talbot, Chicago, Secretary, Section on Stomatology.

well supported, notwithstanding the special organizations devoted to its specialties. The changes in its name indicate fairly well the trend of its work. The following is the list of officers:

| YEAR. | CHAIRMAN.              | SECRETARY.              |
|-------|------------------------|-------------------------|
| 1887  | E. M. Reed (Md.)       | C. B. Bell (Mass.).     |
| 1888  | J. G. Kiernan (Ill.)   | T. C. Evans (Md.).      |
| 1889  | T. B. Evans (Md.)      | T. D. Crothers (Conn.). |
| 1890  | T. D. Crothers (Conn.) | H. N. Moyer (Ill.).     |

#### SECTION ON MEDICAL JURISPRUDENCE AND NEUROLOGY.

|      |                        |                         |
|------|------------------------|-------------------------|
| 1891 | H. N. Moyer (Ill.)     | G. D. Stowbridge (Pa.). |
| 1892 | C. K. Mills (Pa.)      | J. D. Kiernan (Ill.).   |
| 1893 | J. G. Kiernan (Ill.)   | F. P. Norbury (Ill.).   |
| 1894 | D. R. Brower (Ill.)    | W. J. Gavigan (Colo.).  |
| 1895 | T. D. Crothers (Conn.) | W. T. Herdman (Mich.).  |
| 1896 | W. T. Herdman (Mich.)  | C. H. Hughes (Mo.).     |
| 1897 | C. H. Hughes (Mo.)     | H. T. Patrick (Ill.).   |
| 1898 | F. Peterson (N. Y.)    | H. T. Patrick (Ill.).   |
| 1899 | H. T. Patrick (Ill.)   | F. S. Pearce (Pa.).     |

#### SECTION ON NERVOUS AND MENTAL DISEASES.

|      |                         |                         |
|------|-------------------------|-------------------------|
| 1900 | H. A. Tomlinson (Minn.) | F. Savary Pearce (Pa.). |
| 1901 | R. Dewey (Wis.)         | F. Savary Pearce (Pa.). |

## SECTION ON DERMATOLOGY AND SYPHILIGRAPHY.

The Section on Dermatology and Syphilography which was provided for under the same resolution as the preceding, continued under that name till 1898, since which year it has been known as the Section on Cutaneous Medicine and Surgery. It has been officered as follows since its organization:

| YEAR. | CHAIRMAN.                        | SECRETARY.                 |
|-------|----------------------------------|----------------------------|
| 1887  | L. D. Bulkley (N. Y.).....       | F. F. Dunlop (Ky.).....    |
| 1888  | L. D. Bulkley (N. Y.).....       | W. T. Corlett (Ohio).....  |
| 1889  | J. E. Atkinson (Md.).....        | W. T. Corlett (Ohio).....  |
| 1890  | L. D. Bulkley (N. Y.).....       | W. T. Corlett (Ohio).....  |
| 1891  | L. D. Bulkley (N. Y.).....       | J. C. McGuire (D. C.)..... |
| 1892  | L. A. Duhring (Pa.).....         | W. H. Dunlop (N. Y.).....  |
| 1893  | A. H. Ohmann-Dumesnil (Mo.)..... | L. F. Frank (Wis.).....    |
| 1894  | A. E. Regensburger (Colo.).....  | D. H. Rard (Ore.).....     |
| 1895  | L. D. Bulkley (N. Y.).....       | T. C. Gilchrist (Md.)..... |
| 1896  | A. Ravogli (Ohio).....           | T. C. Gilchrist (Md.)..... |
| 1897  | A. W. Brayton (Ind.).....        | T. C. Gilchrist (Md.)..... |

## SECTION ON CUTANEOUS MEDICINE AND SURGERY.

|      |                            |                            |
|------|----------------------------|----------------------------|
| 1898 | W. T. Corlett (Ohio).....  | J. M. Blaine (Colo.).....  |
| 1899 | L. D. Bulkley (N. Y.)..... | R. R. Campbell (Ill.)..... |

Richard Dewey, Wauwatosa, Wis., Chairman, Section on Nervous and Mental Diseases.

|      |                            |                            |
|------|----------------------------|----------------------------|
| 1900 | W. L. Baum (Ill.).....     | R. R. Campbell (Ill.)..... |
| 1901 | H. W. Stelwagon (Pa.)..... | R. R. Campbell (Ill.)..... |

## SECTION ON LARYNGOLOGY AND OTOLGY.

In 1884 an amendment to the constitution was offered by Dr. Carl Seiler of Pennsylvania, which lay dormant till 1888, when it was called up by resolution on the request of the Section on Ophthalmology and the new Section of Laryngology and Otolgy was created. Its officers were elected at the Cincinnati meeting that year and appear in the list below:

| YEAR. | CHAIRMAN.                     | SECRETARY.                 |
|-------|-------------------------------|----------------------------|
| 1888  | W. H. Daly (Pa.).....         | E. F. Ingals (Ill.).....   |
| 1889  | J. O. Iloe (N. Y.).....       | E. H. Potter (N. Y.).....  |
| 1890  | Carl Seiler (Pa.).....        | A. B. Thrasher (Ohio)..... |
| 1891  | C. H. Burnett (Pa.).....      |                            |
| 1892  | E. L. Shurly (Mich.).....     | J. E. Boylan (Ohio).....   |
| 1893  | E. F. Ingals (Ill.).....      | J. E. Fulton (Minn.).....  |
| 1894  | J. E. Fulton (Minn.).....     | T. J. Gallaher (Pa.).....  |
| 1895  | G. V. Woolen (Ind.).....      | M. R. Ward (Pa.).....      |
| 1896  | W. E. Casselberry (Ill.)..... | Braden Kyle (Pa.).....     |
| 1897  | B. A. Randall (Pa.).....      | S. E. Solly (Colo.).....   |

| YEAR. | CHAIRMAN.                   | SECRETARY.                 |
|-------|-----------------------------|----------------------------|
| 1898  | P. R. Holmes (Ohio).....    | Emanuel Mayer (N. Y.)..... |
| 1899  | P. R. Holmes (Ohio).....    | J. A. Stucky (Ky.).....    |
| 1900  | J. N. Mackenzie (Md.).....  | G. C. Stout (Pa.).....     |
| 1901  | G. Hudson Makuen (Pa.)..... | J. F. Barnhill (Ind.)..... |

## SECTION ON MATERIA MEDICA, PHARMACY AND THERAPEUTICS.

At the Nashville (41st) meeting of the Association in 1890, a committee that had been appointed to confer with the American Pharmaceutical Association made its report, as the result of which a resolution was adopted, dropping the words *Materia Medica* from the title of the Section on Practical Medicine, etc., and creating a new Section of *Materia Medica and Pharmacy*, to be added to those already existing. Later, about 1897, its name was changed to the Section on *Materia Medica, Pharmacy and Therapeutics*.

| YEAR. | CHAIRMAN.              | SECRETARY.                 |
|-------|------------------------|----------------------------|
| 1891  | F. Woodbury (Pa.)..... | W. L. Whelpley (Mo.).....  |
| 1892  | F. Woodbury (Pa.)..... | F. E. Stewart (N. Y.)..... |
| 1893  | F. Woodbury (Pa.)..... | F. E. Stewart (N. Y.)..... |

E. Savary Pearce, Philadelphia, Secretary, Section on Nervous and Mental Diseases.

|      |                              |                               |
|------|------------------------------|-------------------------------|
| 1894 | W. L. Whelpley (Mo.).....    | G. F. Hansen (Colo.).....     |
| 1895 | F. E. Stewart (Mich.).....   |                               |
| 1896 | W. B. Hill (Wis.).....       | F. Woodbury (Pa.).....        |
| 1897 | J. V. Shoemaker (Pa.).....   | C. C. Fite (resigned).....    |
|      |                              | L. L. Solomon (Ky.).....      |
| 1898 | F. H. Stucky (Ky.).....      | L. L. Solomon (Ky.).....      |
| 1899 | L. L. Solomon (Ky.).....     | J. W. Wainwright (N. Y.)..... |
| 1900 | N. S. Davis, Jr. (Ill.)..... | J. N. Upshur (Va.).....       |
| 1901 | G. F. Butler (Mich.).....    | C. S. N. Hallberg (Ill.)..... |

## SECTION OF PHYSIOLOGY AND BACTERIOLOGY.

This Section budded off from the Section on Practical Medicine by an amendment offered by Dr. E. A. Wood, which was almost unanimously adopted. Its existence ended in 1901 with its consolidation with the Section on Pathology and Bacteriology to form the new Section on Physiology and Pathology.

A provisional Section on Pathology and Bacteriology had been arranged by correspondence and an unofficial committee appointed by the President, Dr. Keen, for its organization prior to the Atlantic City meeting in 1900. By resolution offered by

Dr. E. D. Ferguson at that meeting this was made a permanent Section and its officers elected. Its existence under this title, however, was short as at the following (St. Paul, 1901) meeting the above-mentioned consolidation and change of name was effected. It was considered desirable to unite the scientific work of the two sections as their separate attendance was small.

For convenience we give the roster of officers of the three sections together.

| YEAR. | CHAIRMAN.              | SECRETARY.              |
|-------|------------------------|-------------------------|
| 1892  | C. H. A. Kleinschmidt  | Ephriam Cutter (N. Y.). |
|       | (D. C.).               |                         |
| 1891  | C. H. A. Kleinschmidt  | Ephriam Cutter (N. Y.). |
|       | (D. C.).               |                         |
| 1893  | I. N. Love (Mo.).      | Ephriam Cutter (N. Y.). |
| 1894  | E. H. Woolsey (Colo.). | C. G. Chaddock (Mo.).   |
| 1895  | H. Bert Ellis (Colo.). | H. Salzer (Md.).        |
| 1896  | A. P. Clarke (Mass.).  | Ephriam Cutter (N. Y.). |
| 1897  | Randall Hunt (La.).    | A. H. Tuttle (Mass.).   |
| 1898  | J. Weir, Jr. (Ky.).    | Lee Kahn (Colo.).       |
| 1899  | Elmer Lee (N. Y.).     | R. Harvey Cook (Ohio).  |

Henry W. Stelwagon, Philadelphia, Chairman, Section on Cutaneous Medicine and Surgery.

#### SECTION ON PATHOLOGY AND BACTERIOLOGY.

1900 L. Hektoen (Ill.). F. B. Wynne (Ind.).

#### SECTION ON PHYSIOLOGY AND PATHOLOGY.

1901 F. B. Wynne (Ind.). J. McFarland (Pa.).

It has been considerable labor to compile even the bald facts above enumerated, partly because of the scattered items in the minutes of the general meetings of the Association, in which changes were made, and partly because of the defective nature of the records. Some years there was no record of the Sections whatever, in others no mention of changes of name, election of officers, etc. The publication of the official section minutes, never complete, has been suspended since the last volume of the Transactions until last year, when it was resumed. All these facts increased the difficulties, and it may be that some important omission has been made. It is believed, however, that with possibly one or two such this record is reliable.

#### Association Officers.

The following is a list of the principal officers of the Association from its inception to 1902. The dates given are those of their election, except in the case of those appointed to deliver the annual addresses. The years given in their case are those in which the actual service was performed. The section officers are given elsewhere in the history of the sections.

In the early years of the Association two secretaries were elected annually; both are included in the list. Since the office of permanent secretary was provided for there has been for many years an assistant local secretary appointed each year; these are not included.

**Treatment of Uncontrollable Vomiting by Saline Injections.**—Dr. R. Condamin of Lyons, France, treats patients with uncontrollable vomiting of pregnancy by rectal injections of 3 to 4 quarts of tepid saline solution fractionated during the day, not more than 300 gm. at a time. This combats the auto-intoxication which he assumes to be the cause of the vomiting and, supplemented by absolute withholding of all food, has cured eight severe cases in his experience, without the necessity of artificial delivery which otherwise seemed to be imperatively indicated.

**Treatment of Bites.**—Bujwid condemns the practice of thermocauterizing bites as it is almost inevitably done too late and is only superficial at best. It also produces a defect or deformity of the part. He recommends the use of tincture of iodine for the treatment of a bite in a communication to the *Przegląd Lekarski*.

Subscription price: Five dollars per annum in advance

SATURDAY, JUNE 7, 1902.

## PERMANENT SECRETARIES FOR THE SECTIONS.

By reference to the history of the Sections, printed elsewhere in this issue, it will be noted that with one exception each of the Sections makes it a rule to elect a new secretary each year. We know of no other medical society, or, for that matter, any organization, that changes its secretary annually. A thought given to the subject will call to mind the fact that every successful medical society makes the office of secretary a more or less permanent one. This is because it is recognized as practically necessary for continued good work and for the carrying out of a definite policy.

The work connected with arranging a program is such that but few men are successful at it the first year. It requires certain knowledge that can only be had by experience. It is not every one who knows what constitutes a good program. Three years ago an earnest secretary of one of the Sections joyfully remarked that he had a splendid program, having nearly ninety titles. When his attention was called to the rule limiting the number of papers he was crestfallen. A few good papers, and these well discussed, will make a good meeting always; a lot of papers, with no time for discussion, will make an unsatisfactory meeting always. This is not known by the average secretary the first year, although he learns it by experience. There is an art in arranging titles so that papers bearing on the same subject can be read and debated together. In this regard the programs of some of the sections this year, as they do each year, show lack of a recognition of this principle on the part of those who arrange them.

The Sections, more than ordinary societies, should have a more or less permanent secretary on account of the peculiar relation they hold to the profession as a whole, and the necessity for the use of good judgment in accepting what may be offered, as well as on account of the rules governing them.

Each Section has, in large measure, an autonomy of its own, and yet with one, possibly two, exceptions they have no records, no rules. A former chairman of one of the Sections, Dr. H. T. Patrick, in his address called attention to the necessity of a permanent secretary, and, among other things, said:

And this leads me to another point. When, raw and callow, I first assumed the duties of secretary, I was astonished to learn that not a line of record, correspondence, instruction, precedent, hint or suggestion descended to me from my predecessor. For fourteen years motions had been made, amended, lost, car-

ried and had quietly slipped into oblivion, leaving no trace behind. Policies had been endorsed and rejected, resolutions adopted, committees had been appointed, had reported and been discharged, and not a minute made. I submit to you that this is a slipshod way of conducting affairs.

What Dr. Patrick found true as regards the Section on Nervous and Mental Diseases we found true of all Sections in writing up their history.

Each Section should have its own by-laws, subject, of course, to those of the American Medical Association, its own book of records, a general but fixed policy as to the scope of the scientific work it will cover, so that two, three and four Sections will not hereafter be found covering the same ground at the same annual session of the Association. To do all this there must be a continuation in office somewhere, and the only place it is possible is in the office of secretary.

As a rule, however, one who has been secretary for one year will hesitate to accept the office the second time. He has quite likely found his work wearisome, vexatious and unsatisfactory from various avoidable causes; when he has once "learned the ropes," the work will become simple, easy, and positively a pleasure. When we are urging the Sections to adopt this principle we are not suggesting something new; time and again in the past THE JOURNAL has advocated the same. Many of the Section officers, also, have done likewise.

## A VOLUNTARY NATIONAL EXAMINING BOARD.

Dr. Rodman's communication in this issue, to which we wish to specially call attention, ought to clear up the atmosphere materially as regards the proposition of a voluntary national board of examiners. His plan is, in a way, a complete one, and he gives good reasons why it ought to succeed. In fact, he meets all the objections that are worth consideration very fully and fairly, and we do not see why his plan might not be adopted at once. It can easily be made elastic as to the place of examination, and as it is as probable that as large a percentage of graduates in western medical schools as of those of eastern ones would want to take the examination, it should be held also at other medical centers than those he mentions exclusively. We do not see any very serious difficulties in effecting this and thus obviating the only very serious objection raised to the plan.

The discretionary power suggested as regards specialists and men who have already made their reputation in medicine can be safely exercised by such a board as the one proposed, and hardly as well by any other. It is farcical to demand of one whose reputation is an honor to the profession of his country the same elementary and minute examinations as must be given the recent graduate, but any deviation from the rule must be carefully guarded, and hence the necessity of some possible detail as to this point—perhaps something like a special session of the board as a supreme council in such a case. Such matters, however, can be safely left as a detail to a body constituted as is the one proposed, representing the very highest elements of the

All but Fig. 40 from unstained specimens.

profession and fully commanding its confidence. Doctor Rodman does not notice one possible demand, that of sectarian representation on the board, but we believe that with assured perfect fairness and restriction of the examination to essentials, without lessening its thoroughness, this demand will be practically silenced. It is believed that with the present trend of tendency in medical matters, and with the experience of the past, even the better class of the medical sectarians will seek the one national qualification.

Our Canadian confrères have just succeeded in obtaining a board, giving what will doubtless be a universal qualification for their territory, under constitutional difficulties almost identical with those we meet on this side of the line. In their case the board is made up of representatives of the provinces, and no province is represented on it that does not legally endorse its qualifications. What they can do in one way is equally practicable for us in another, and it is to be hoped that the movement will soon be well under way. It is a matter that demands the early attention of the Association through its delegated body, and also of the meeting of representatives of the state boards, which is to be held at about the same time. A co-operative action on the part of both will go far to put the project on a sound basis and insure its early success.

#### THE INTERCOMMUNICABILITY OF HUMAN AND BOVINE TUBERCULOSIS.

There is at the present day no difference of opinion as to the communicability of tuberculosis from one human being to another, or from an animal of a given species to another animal of the same species. Some doubt has been raised, however, as to the identity of the tubercle bacillus of human beings and that of lower animals. The question is of the utmost importance, as upon its decision must depend the measures to be instituted in the movement that has been set in action over the entire civilized world looking to the suppression of the great white plague, or, at least, the restriction of its ravages.

The startling announcement of Robert Koch at the British Congress for Tuberculosis to the effect that human and bovine tuberculosis are independent and non-communicable—a statement in direct contradiction of the view previously expressed by him—is still fresh in mind, but despite the acknowledged authority of this distinguished bacteriologist, not alone was his statement not accepted, but it was in fact at once taken issue with. Evidence was presented indicating the falsity of the new position and the machinery was immediately set in operation to secure data to establish with accuracy its correctness or incorrectness. One of those whose voices were raised against the revolutionary doctrine was an American—Dr. M. P. Ravenel, Bacteriologist to the State Live-stock Sanitary Board of Pennsylvania—who had facts at hand and presented in one of the sections of the congress a communication, demonstrating be-

yond peradventure of doubt the intercommunicability of the disease between man and cattle. Dr. Ravenel has continued his studies in the same direction and some of his results are detailed in a paper read recently before the Pathological Society of Philadelphia.<sup>1</sup> After citing evidence from many sources as to the transmissibility of tuberculosis to animals of the bovine species by means of intestinal, intravenous, subcutaneous, intraperitoneal, intraocular, intrameningeal inoculation of tuberculous material from human beings, he details observations of a similar and corroborative nature made in the laboratory of the State Live-stock Sanitary Board of Pennsylvania. The evidence thus seems indisputable that tuberculosis is transmissible from human beings to cattle. That as to the transmission of the disease from cattle to man can, in the nature of things, be only indirect, but such as exists points indubitably in that direction.

It is not denied that there are differences between the lesions of tuberculosis as seen in human beings and in cattle, but these cannot be considered essential. There are also certain morphologic and cultural differences, as well as differences in virulence, between the respective tubercle bacilli, but these are not constant and invariable.

From the mesenteric gland of a child dead of tuberculous meningitis a culture of tubercle bacilli was obtained that exhibited the most intense pathogenic virulence for cattle. The micro-organisms in this case are believed to be bovine tubercle bacilli because the infection of the child was primarily intestinal, because of the morphologic and cultural correspondence of the organisms to the bovine type, and because of their great pathogenic activity for cattle. Cultures from the mesenteric glands of a second child also dead of tuberculous meningitis likewise exhibited a virulence in excess of that ordinarily observed in cultures of human tubercle bacilli, though less than that described in the first instance.

There are on record a not inconsiderable number of cases in which accidental infection of human beings with bovine tubercle bacilli has taken place. Certain difficulties surround the demonstration that tuberculous infection takes place in human beings through the ingestion of tuberculous milk and meat, inasmuch as the invading micro-organisms may pass through the intestinal wall, the mesenteric glands, the thoracic duct and the venous circulation, to be deposited in the lungs, as has been shown experimentally. At the same time intestinal and mesenteric tuberculosis are far from rare in children, and they may fairly be attributed to infection through the food.

It is probable that we have in the past had an exaggerated notion of the frequency with which tuberculosis in human beings is acquired from cattle, but, after all due allowances are made, the fact remains that the danger from this source is a real one, and so far

1. Univ. of Penna. Medical Bulletin, May, 1902, p. 66.

as possible steps should be taken to reduce it to a minimum. Accordingly care should be still taken not only to prevent dissemination of the discharges from cases of tuberculosis in human beings, but also to limit the disease in cattle and other animals and to prohibit the use of milk and meat from tuberculous animals.

In the opinion of Ravenel, which seems to be amply justified by the available evidence, the various types of tubercle bacilli have sprung from a common stock, and they have acquired their racial peculiarities by residence in different animals by reason of differences in nutrition, temperature and resistance. In each instance the tubercle bacillus acquires properties that best enable it to maintain its existence in the particular host. The conclusion therefore seems justified that human and bovine tuberculosis are but slightly different manifestations of the same disease and are thus intercommunicable.

#### THE PANCREAS IN DIABETES.

The interest in the relation of diabetes to lesions in the pancreas has been much increased by the recent demonstration of more or less definite changes in the so-called islands of Langerhans in many cases of this disease. The final explanation of diabetes must be sought by chemical methods, and the recent work of Herter and others on adrenalin diabetes, to which reference has been made in these columns from time to time, is extremely suggestive and important. In the meantime the finer morphologic changes that there is good reason to believe may constitute the anatomic substratum of spontaneous pancreatic diabetes will appeal to many as an interesting field of research. No doubt many facts of value will accumulate in time from investigations in this line.

At present interest centers especially in the islands of Langerhans, these peculiar glomerulus-like, minute structures that have the same general cellular make-up in the majority of mammals and birds, but which seem to have escaped recognition until within the last three or four years. According to Ssobolew,<sup>1</sup> who was among the very first to pay any attention to the Langerhans islands, they are best developed in small animals with intense metabolism, such as the guinea-pig and the pigeon. The largest islands are found in man and in guinea-pigs. They are prominent early in life and in the human fetus they are present at the sixth month. In no case have the islands any ducts, hence it has been customary to speak of them as ductless islands with an internal secretion as distinguished from the more familiar glandular secretions that are poured out upon any mucous and cutaneous secretions. Ssobolew reasoned that if the islands are anatomically and functionally distinct from the ordinary digestive apparatus of the pancreas, then they would not be affected by ligature of the pancreatic ducts, which would throw the digestive functions out of play and thus lead to atrophy of the secreting

cells. His results obtained after ligature of the pancreatic duct in rabbits, cats and dogs confirmed this conception, because while the digestive structures disappeared the islands of Langerhans persisted practically unchanged and diabetes did not appear. Ssobolew assumes that the islands survive after ligature of the duct because they continue their function under the influence of "trophic influences," their metabolic activities not being disturbed by the retention of the pancreatic digestive juice. Ssobolew also finds that in transplantation of the pancreas, Langerhans' islands are the most persistent, and as long as they are intact diabetes does not develop. And in atrophy of the pancreas the islands remain longer than the digestive part of the gland, thus again indicating that they are, in a measure at least, independent of the main mass of the pancreatic tissues. In fifteen cases of diabetes, Ssobolew found more or less well-marked changes in the Langerhans islands in practically all the cases, and he points out that in diabetes they appear to be the least resistant parts of the pancreas. Unfortunately Ssobolew, in his review of the literature on the changes in the pancreas in diabetes, omits entirely references to the American literature. Had he not done so, but studied American articles as thoroughly as those in other languages, he would have found definite mention of the islands in more than four of 405 cases of diabetes which he cites as showing the neglect of careful study of these interesting areas.

The anatomic isolation of the islands of Langerhans by ligature of the pancreatic duct and the absence of diabetes under these circumstances certainly point to them as the anatomic substratum of the sugar-splitting functions of the pancreas. This is further supported by the changes that are now being described in the islands in cases of human diabetes. And it may not be too far-fetched to suggest that eventually some form of organotherapy of diabetes may develop as the result of experienced and anatomic investigations of this kind.

#### THE HYSTERICAL SAN FRANCISCO PRESS.

A California court has decided that the old board of health of San Francisco can not be ousted except by quo warranto proceedings, thus annulling the Mayor's removal. San Francisco and California are to be congratulated that this decision leaves those in office in whom the rest of the country can have some confidence. The San Francisco papers, however, are still denying that there has ever been an instance of plague in that city and hysterically howling at the decision. One of them calls it a "deplorable hair-splitting decision," and repeats the old charge of the injection of dead Chinamen with plague cultures, and dilates on the subject generally as if the respectable physicians comprising the board, the officials of the Marine-Hospital Service, the U. S. Government Commission, and, in short, the medical profession of the state and country were allied with the rival ports in a conspiracy against the commercial interests of San Francisco. It is not easy to reconcile

1. Virchow's Archiv, last issue.

this course with ordinary common sense, to say nothing of common honesty and decency. It is altogether beyond rational explanation why the newspapers of San Francisco can not take a sensible course in regard to the plague cases which undoubtedly have occurred in that city. The world knows the facts, that is, it knows that plague cases have occurred, and frantic denials are not going to change the facts. There is a danger, however, that protesting too much may increase suspicion and lead people to think that worse remains behind: the course of the Governor and Mayor has just this tendency. The correct way would be to admit the facts, which in themselves are not, so far, very formidable, encourage open and free investigation and generally act so as to convince the world that there is nothing held back and that the authorities are intelligently alive to the situation and its needs. Let the ostrich policy be continued, however, and a plague case get away from San Francisco and develop elsewhere and there would then be serious trouble for them, entirely beyond their control and power of concealment. There should be enough sensible business men in San Francisco to have some inhibitory control over the performances of the mayor and the utterances of the local press. It seems hardly conceivable that the sober, sensible element in the community should be so impotent in this respect, as it must be if matters are to continue as they have been in the past. A word to the wise is sufficient. It is hard to say how many must be addressed to be effective with the San Francisco Mayor and his subservient organs of the press.

#### A MATTER REQUIRING ATTENTION.

Our Washington correspondent sends us the following telegram, which is of interest to the profession, and will, we hope, be duly considered by every individual member:

WASHINGTON, D. C., June 3, 1902.

The bill retiring Surgeon-General Sternberg with the rank of major-general, which passed the Senate unanimously and was favorably reported by the entire House Committee on Military Affairs, was defeated in the House yesterday afternoon. Mr. Cannon of Illinois and Mr. Underwood of Alabama were very active in their opposition. Mr. Underwood of Alabama practically sneered at and insulted on the floor of the House of Representatives every member of the American Medical Association and of the state societies. His remarks and those of Mr. Cannon and others will be incorporated in the report of the Committee on National Legislation, and will be specially called to the attention of the American Medical Association at its meeting at Saratoga Springs, N. Y., June 10. The *Congressional Record* of June 2, pages 6620 to 6625, containing the full debate in the House of Representatives on the bill retiring Surgeon-General Sternberg should be read by the entire medical profession.

The medical profession in Illinois and Alabama, as well as in other states whose representatives voted against the bill, is strong enough to show its power and make it respected even by politicians. Forbearance to a certain extent is a Christian duty, but we have been here smitten enough on both cheeks to make it no longer a virtue. When a congressman goes out of his way to insult an honorable profession, collectively and individ-

ually, he is unfit for his position, and it is our duty as citizens to use all our influence against him. Further comment is needless.

#### HOSPITAL DEADBEATS.

A prominent surgeon in Brooklyn has started a good work in instituting legal proceedings for the collection of certain bills from hospital patients of his who were able but unwilling to pay for his services. Their contention that as hospital patients they were entitled to his service gratis is a poor defense morally, and we trust it will also be found such legally. Physicians give their services to hospitals in the treatment of the poor, but that does not follow that they also give them to the undeserving rich. We are not aware that the question here raised has ever been passed on by a court, but there is no question as to the abstract justice of the Brooklyn surgeon's demand. With the multiplication of hospitals, which is the order of the day, the matter is an important one, and we hope and trust that he may win his suit. If it should be decided that only charity medical practice is permitted in public hospitals, or that it is always implied in such institutions except where it is otherwise expressly stipulated, then let the hospitals use a better discrimination in their admissions and hospital surgeons and physicians make this a prerequisite for their services. The medical profession is not to be always considered a "soft snap" for well-to-do impostors. There has been enough of that in the past, is altogether too much now, and what there is to be in the future is a matter for us to seriously consider. The surgeon in question is doing a service to his professional brethren in thus instituting his suits. The results will be serviceable as a future guide to the profession, and, if he succeeds, a valuable legal precedent.

#### RELATION OF PHYSICIANS TO EMBALMING.

The proper embalming of a dead body requires considerable technical skill and judgment, and a large majority of undertakers are entirely incapable of performing it in a satisfactory manner. J. G. Garson<sup>1</sup> considers that embalming should not be relegated to the undertaker, but should always receive the direct attention of the medical attendant of the deceased. The injection of an antiseptic solution into the large serous cavities of the body may undoubtedly have some effect in reducing the rapidity of decomposition, but it does not compare in efficiency with the introduction of the antiseptic solution directly into the blood vessels. By this latter means the various parts of the entire body are most universally reached by the antiseptic. The proper injection of a body through the blood vessels requires no little care in regulating the pressure to be brought upon the vessels. The perfunctory embalming, which is usually carried out as soon after death as possible by undertakers, has for its chief result the ability of the operator to add another item to his bill. If consent for an autopsy has been obtained some time after death, the previous introduction of corroding and discoloring solutions has frequently prevented any information of value being obtained at the examination. In medicolegal cases much damage has resulted from early

1. *Lancet*, May 10, 1902, 1301.

embalming. Whether the embalming is actually done by the physician or not, no body should be embalmed until his consent has been obtained. Garson prefers to make the injection into the abdominal aorta just below the umbilicus. In many cases a physician could obtain useful information through a small abdominal incision made in the process of embalming, and when no systematic autopsy could be obtained this might be of great value. It would seem to be very desirable for the attending physician to be present at the operation even if not actually performing it, and to make use of the opportunity for observing the condition of the principal viscera through the incision made for purposes of embalming the body.

#### PERMANENT TENURE OF OFFICE FOR HEALTH OFFICERS.

In the discussion of "some problems in municipal sanitation from an executive standpoint," W. C. Woodward,<sup>1</sup> Health Officer of the District of Columbia, says that the difficulty in securing competent officers in the contagious disease service and competent chemists and bacteriologists to take charge of the laboratories arises chiefly from the uncertain tenure of office and the inadequacy of compensation. The British Medical Association has been instrumental in securing the introduction in the House of Commons of a bill which seeks to amend the law relating to the tenure of office of medical officers of health and sanitary inspectors. In England, at present, the medical officer of health is appointed for one, three or five years, and the sanitary inspector for one year. The bill provides that properly educated and qualified men shall be appointed to these offices and shall be secure in their positions as long as they perform their services satisfactorily. The duties of officers of health are indicated by the teachings of modern science and can not vary with the whims of each new mayor or governor who happens to be elected to office. Matters of public sanitation have become so manifold that special education and experience are necessary for the proper administration of them. The public can only obtain the best service when those who look after the public health are secure in their positions as long as their duties are properly performed, and when they are relieved of the distracting necessity of keeping on the right side of politicians in order to retain their places. The treatment of medical health officers in one of our western cities at the hands of lay authorities, who claim to determine the absence of plague by their individual feelings and desires, is most deplorable, and has subjected the rest of the country to a most unnecessary danger. The absolute separation of all matters of public health and hygiene from changeable politics is much to be desired and is to be constantly sought by the medical profession.

#### THE MYASTHENIC SYMPTOM-COMPLEX.

There have been reported in recent years a small number of cases characterized by undue readiness of fatigue in certain groups of muscles, especially those supplied by the bulbar nerves, occurring in attacks, without alteration in sensibility, in nutrition and in reflex activity. The irritability of the affected muscles is, further,

quickly exhausted by electric stimulation, constituting the myasthenic reaction. The nature of these cases is obscure and in the absence of more definite knowledge and of evidence of organic disease they have been thought to be of toxic origin. That they may be of varied pathology is suggested in a recent communication by Dr. Jenő Kollarits,<sup>1</sup> who reports two cases presenting typical symptoms of myasthenia, also a case of cerebellar tumor studied clinically, one of cerebellar tumor and sarcomatous infiltration of the spinal pia mater with postmortem examination, and one of exophthalmic goiter, in all of which the so-called myasthenic reaction was present. As a result of his observations he expresses the opinion that the myasthenic symptom-complex comprises various disorders, namely, familial affections characterized by attacks of weakness or paresis, although permanent symptoms may also be present; conditions developing in the sequence of febrile disorders or attended with fever—these are to be classed with polio-encephalo-myelitis; cerebral lesions; the incipience of diseases the diagnosis of which can be made only after considerable observation. The absence of anatomic lesions, it is believed, is not sufficient to make a case one of myasthenia; nor does the development of muscular atrophy and of degenerative electric reactions exclude the possibility of myasthenia; while exhaustibility of the muscles and the exhaustion reaction have only limited diagnostic significance. The so-called myasthenic reaction of the muscles does not differ essentially from that which had previously been described as the fatigue reaction and which had been observed in cases of hemiplegia, progressive muscular atrophy and dystrophy, paralysis agitans, anterior polio-myelitis and Landry's paralysis. The myasthenic reaction has been recorded as being present, further, in cases of tabes dorsalis, cerebellar tumor, neurasthenia, traumatic hystero-neurasthenia, multiple sclerosis, and organic disease of the pons. As a substitute for both terms the designation "exhaustion reaction" is proposed.

#### DOMESTIC ANIMALS AND INFECTIOUS DISEASES OF MAN.

Although most of the infectious diseases which affect the lower animals are not transmissible to man, there are certain diseases to which both man and some domestic animals are susceptible and which may be directly transferred from such animals to the human subject. The probability that man may acquire tuberculosis by infection through milk which contains tubercle bacilli has been brought forward by sanitarians so prominently that the laity is now fully alive to the danger of using milk from tuberculous cows. Man also contracts glanders from horses, actinomycosis from cattle affected with lumpy-jaw, and hydrophobia from the bite of rabid dogs. People do not usually know that domestic animals may be dangerous as carriers of infections of other sorts. Cats and dogs have been known to be the means of carrying the infectious agents of diphtheria and scarlatina from one child to others. Beside acting as the simple vehicle for the infectious materials, there is some evidence in favor of the belief that cats may be affected with both these diseases and so become a source

1. Phila. Med. Jour., May 17, 1902, 889.

1. Deutsches Archiv für Klinische Medizin, B. 72, H. 2, p. 161.

of danger to the families in which they live. Plague is also said to occur in cats and they have been accused of spreading the infection in this disease. There has been much discussion over the etiology of ozena, and the most recent workers upon the subject appear to have shown that the bacteria formerly described as the exciting agents are not such. Perez<sup>1</sup> has described a bacillus which he believes to be the cause of ozena, and he has found it to be a common inhabitant of the nasal cavities of dogs. It is his belief that the dog is the source of the infection in man, and he found that several persons who were affected with the disease had played much with dogs. As prophylactic measures against ozena he advocates the prevention of too close contact with dogs, especially by children, and the avoiding of contact between healthy persons and those afflicted with the disease. The possible danger of infection with the specific agent of ozena through close contact with dogs, as when the animal is allowed to lick the face, is not the only reason why the affectionate demonstrations of dogs should be restricted. Echinococcus disease is probably acquired by close relationship between dogs and persons of unclean habits. When one considers the habits of the ordinary city dog, it is not difficult to imagine that it may carry about the ova of various intestinal worms and other infectious agents upon its nose, and readily deposit them upon the hands and face of people when occasion offers. People are to be warned of the danger of pets as carriers of infections, especially scarlatina and diphtheria, and sick domestic animals should always be looked upon with suspicion.

## Medical News.

### CALIFORNIA.

**Van Slyck Dinner.**—The medical men of Pasadena testified to their esteem for Dr. David B. Van Slyck by giving him a banquet on the occasion of his half century of medical life, at which a silver loving-cup was presented to him.

**Hospital to be Built.**—Within a few days ground will be broken at San Francisco for St. Mary's Help Hospital. At present only the foundation and one story will be built, as the funds subscribed will not warrant a further outlay. The ultimate intention, however, is to erect a building to cost \$250,000.

**Injunction in Force.**—The San Francisco Board of Health removed by the Mayor because they held to the truth in the matter of the bubonic plague in San Francisco, will remain in office for a time, at least, as the injunction restraining the new appointees from interfering with the old board has been continued in force.

**New Hospital in Berkeley.**—A new sanitarium association has been incorporated by physicians and business men of Berkeley and Oakland. Dr. Samuel H. Buteau, Oakland, and Drs. Hubert N. Rowell, Charles F. Gladding and Edwin A. Kelley, Berkeley, are members of the board of directors. Immediate accommodation for twenty-five patients will be provided pending the erection of a new hospital.

### COLORADO.

**Gift to Sanitarium.**—The Hon. Bellamy Storer, United States Minister to Spain, has given \$2000 to the annex-building fund of Glockner Sanitarium, Colorado Springs.

**Bellevue Hospital.**—Bellevue Hospital Association, Colorado Springs, was incorporated, April 21, officers chosen, and Dr. James A. Hart elected advisory medical supervisor.

**Gross Medical College, Denver.** graduated a class of 22, two of whom were women, May 16. Rev. Frost Croft delivered the address and Chancellor Dr. Wm. Herman Buechel conferred the degrees.

**Cripple Creek Hospital Opened.**—The new Teller County Hospital at Cripple Creek, erected at a cost of \$21,000, was opened, May 13. Dr. Alexander C. Magruder, county physician, is in charge.

### DISTRICT OF COLUMBIA.

**Competitive Examination for Internes.**—As a result of the examination for internes at the Emergency Hospital, Washington, the senior position was won by Dr. R. L. Sutton, Kansas City, Mo.; the junior, by Dr. A. J. Cashman of Washington, D. C. Eight applicants took part in the competition.

**Johnston Memorial Hospital.**—In recognition of the services rendered by the late Dr. William W. Johnston to the medical profession in general and to Columbian University Hospital in particular, the officials of that institution have decided to designate the new building, which has just been begun, the "Johnston Memorial Hospital."

**Howard's Graduates.**—The largest class ever graduated from Howard University, Washington, received diplomas at the thirty-fourth annual commencement of the institution, May 6. President Rankin conferred degrees on 27 students; Dr. John E. Brackett gave the charge to the class and Rev. Dr. Horder of London, England, made an address.

**Medical Inspectors for Schools.**—The draft of the substitute bill sent to the Senate District Committee by the District Commissioners relative to the appointment of medical inspectors for the public schools, reads as follows:

For eleven medical inspectors of public schools, to be appointed by the Board of Education of the District of Columbia, at \$500 each, \$5,500;

Provided, that said inspectors shall have had at least five years' experience in the practice of medicine in the District of Columbia, and shall only be appointed after a competitive examination.

### ILLINOIS.

**Corbyn Memorial Bed.**—The directors of the Dr. Corbyn Memorial Society have decided to endow in perpetuity a free bed in Blessing Hospital, Quincy, at a cost of \$4000.

**Accident to Dr. Moore.**—In a runaway accident near Dixon, May 20, Dr. Amos F. Moore was thrown from his buggy, sustaining a fracture of the left leg below the knee, and numerous cuts from contact with a barb-wire fence.

**Pavilion for Alton Hospital.**—Through the beneficence of a lady who does not care to have her name mentioned, work has already commenced on a large open-air pavilion to be erected on the north side of St. Joseph's Hospital, Alton.

**Dr. McCord's Anniversary.**—On the occasion of the birthday anniversary of Dr. T. Chester McCord, Paris, major and surgeon, Fourth Infantry, 1. N. G., about 25 of his professional associates showed their appreciation of his sterling worth by giving him a reception.

### Chicago.

**Appropriation to Combat Smallpox.**—Funds for the health department's fight on smallpox were voted by the council finance committee, the recommendation being made that \$15,000 be appropriated. The department has been severely hampered for lack of funds, and Commissioner Reynolds recently asked for \$50,000.

**New Internes.**—On June 2, nine new internes, Drs. P. Koehler, H. Snyder, J. Carr, C. E. Sears, W. G. Dunn, G. W. C. Parker, W. E. Engelbarr, G. I. Barber and C. W. Howard, began their work at the County Hospital, relieving Drs. D. E. W. Wenstrand, J. F. Hultgen, W. R. Tyndale, W. R. Cubbins, I. McNeill, E. C. Reibel, R. F. Palmer, J. F. Howard, E. N. Nash, J. N. Axelsson and A. Foeter, whose terms of service have expired.

**Comparison of Mortality in Cities.**—The Chicago mortality rate for the year 1901 was 13.65 per 1000 of the estimated midyear population, 1,758,025, and was 21 per cent. lower than the St. Louis rate, 25 per cent. lower than Philadelphia, 30 per cent. lower than Boston, and 35 per cent. lower than New York, even allowing these cities estimated populations based on much higher rates of increase than that claimed for Chicago.

**County Hospital Items.**—The quarantine placed on the children's ward a week ago because of diphtheria has been raised.—It is recommended that more nurses be employed in place of the convalescents who now serve as "day men" in each ward.—The officer-of-the-day advocates that hospitals be notified that the hospital does not admit chronic and incurable patients whose proper habitat is the county institution at Dunning.—The warden has appealed to the city for aid in caring

1. *Annal. de l'Inst. Pasteur*, May 25, 1901.

for contagious diseases, as the ward in the hospital is full to overflowing.

**May Mortality.**—There were 2128 deaths from all causes in May. This is a decrease of 144 over the previous month, April, but eighty-two in excess of the figures for May, 1901. Notwithstanding this excess, the rate per 1000 of population is substantially the same—1370 for May, 1901, and 1375 for May, 1902. In the first five months of the current year 11,223 deaths have been recorded, as against 10,293 in 1901, an excess of 9 per cent. in number and of 5.2 per cent. in proportion to population. More than one-half the excess thus far this year comes from the age group under 5 years, and of this the period between 1 and 5 years contributes \$1 per cent. The acute respiratory diseases, bronchitis and pneumonia, have been especially rife and unusually fatal among children at these ages, and scarlet fever has also been excessively prevalent. Infants under 1 year of age contribute 9.5 per cent. of the excess, while the aged, those over 60 years, show a slight decline. The record of fifty suicides in the month is the highest yet made, and the number of deaths from Bright's disease, 134, is also unprecedented.

#### IOWA.

**Donation to Mercy Hospital.**—Mrs. Benjamin Thaw, formerly of Cedar Rapids, but now a resident of Pittsburg, Pa., has given \$1000 towards the new Mercy Hospital in the former city.

**Tribute to Dr. Middleton.**—At the quarterly meeting of the Iowa and Illinois District Medical Society, the evening was devoted to memorials of its ex-president and long-time member, the late Dr. William D. Middleton of Davenport.

**Dr. Braunlich Recovering.**—Dr. H. U. Braunlich, Davenport, who for many weeks hovered between life and death suffering from septic poisoning, has at last been declared convalescent. His infection occurred at the same operation in which the late Dr. Middleton received the slight but fatal abrasion of his thumb.

#### MAINE.

**Dr. Nathaniel T. Palmer,** one of the leading citizens of Brunswick, and one of the founders of the Maine Medical Society, recently celebrated his eighty-fifth birthday.

**Golden Wedding.**—On May 11, Dr. and Mrs. Franklin B. Ferguson, Deer Isle, celebrated the fiftieth anniversary of their marriage. For forty-eight years Dr. Ferguson has practiced medicine in Deer Isle.

**Sisters' Hospital Dedicated.**—Bishop O'Connor of Portland recently dedicated the new Sisters' Hospital at Lewiston. The building has now accommodation for 75 patients, and its full capacity in case of necessity will be 200 beds.

**Damages Awarded.**—In the damage suit for \$10,000 brought by the widow of Henry F. Ramsdell against Dr. James B. Grady, Eastport, on account of his alleged neglect of her husband, the jury awarded the plaintiff damages of \$3000.

#### MARYLAND.

**State Board of Pharmacy.**—The governor has appointed the first State Board of Pharmacy Maryland has ever had, consisting of William C. Powell, Snow Hill; J. Webb Foster and David R. Millard, Baltimore; Charles B. Henkel, M.D., Annapolis, and William E. Turner, of Allegany County. The Board met for organization at Baltimore May 8, and elected Dr. Charles B. Henkel, president; W. C. Powell, treasurer, and D. R. Millard, secretary. The first examination was held May 28.

#### Baltimore.

**Mortality.**—For the week ending May 31, there were 168 deaths, consumption leading with 25.

**Many Patients at Pasteur Institute.**—There are now sixteen patients in the Pasteur Institute at the City Hospital, the largest number in the history of the institution.

**The Commencement of the Woman's Medical College.**—This commencement was held May 30, there being four graduates. Hon. George Savage, chief judge of the Orphans' Court, delivered the oration.

**The Johns Hopkins Endowment.**—About \$120,000 is still needed to make up the million-dollar endowment of the Johns Hopkins University, but the committee of 70 is confident of raising the entire sum by July 1.

**The Magness Matter.**—A dispatch from Parkersburg says that when the case of Dr. Thomas H. Magness of Baltimore, who was indicted on the charge of impersonating a medical

student, David R. Shepler, and taking the medical examination of West Virginia in his name, was called on May 29, Dr. Magness was not present and default of his bond of \$500 was entered.

**Personal.**—Dr. L. McLane Tiffany has resigned the chair of surgery in the University of Maryland and has been elected emeritus professor of the same branch.—Dr. A. Aldridge Matthews has been appointed superintendent of the University of Maryland Hospital, vice Dr. George H. Stewart, resigned.—Dr. William Osler has returned from Atlantic City and resumed his professorial duties.—Dr. Herbert Harlan, professor of ophthalmology and Dr. Francis M. Chisolm, associate professor of the same branch in the Woman's Medical College, have resigned.—Dr. Joseph Clement Clark, professor of psychiatry in the same institution, has been elected to the same chair in the Baltimore Medical College.

#### MASSACHUSETTS.

**Newton Hospital Additions.**—Two additions to the Newton Hospital were formally opened May 15—the new north pavilion of the contagious ward and the new Thayer ward for men.

**Chiropodist Fined.**—Edward E. Willard, a chiropodist of North Adams, was recently found guilty of the illegal practice of medicine and was fined \$100. As he was unable to pay the fine he is now serving a sentence of three months in jail.

**Appropriation for State Sanatorium for Tuberculosis.**—On May 22, after a hard fight, Senator Fitzgerald obtained the passage of a bill appropriating \$150,000 for an additional building at the Sanatorium for Consumptives at Rutland. On account of lack of accommodations, 484 applicants were refused admission to the sanatorium last year.

**Cooley-Dickinson Hospital.**—At the annual meeting of the trustees of this hospital, at Northampton, Dr. Christopher Seymour was reelected president of the board. The following staff was appointed for the year: Medical—Drs. James M. Fay, George D. Thayer, John S. Hitchcock and Arthur G. Minshall. Surgical—Drs. Alfred H. Hoadley, James C. Fahey, Edward W. Brown and H. D. Perry. Oculist—Dr. Clarence R. Gardner, and consulting bacteriologist, Dr. Herbert C. Emerson, Springfield.

#### OHIO.

##### Cincinnati.

**City Hospital Officers.**—At the May meeting of the staff of the Cincinnati Hospital Dr. S. A. Fackler was elected president for the ensuing year; Dr. B. K. Rachford, vice-president; Dr. Arch. I. Carson, secretary; Dr. P. S. Conner, librarian.

**Society of Internes Meet.**—Dr. J. C. Oliver has been elected president of the Society of Internes of the Cincinnati Hospital. Nearly one hundred members attended the annual banquet held at the Phoenix Club the evening of May 17.

**Miami Medical College Changes.**—The faculty of the Miami Medical College announces the following additional changes in their personnel for the session of 1902-3: Dr. J. C. Oliver, dean and professor of operative surgery; Dr. C. E. Caldwell, professor of orthopedic surgery; Dr. Magnus A. Tate, lecturer on embryology; Dr. M. L. Heidingsfeld, clinical lecturer of dermatology and venereal diseases.

**Personal.**—Dr. Nora Crotty, recent graduate of the Cincinnati College of Medicine and Surgery, has left for Europe to take post-graduate studies in Vienna.—Dr. P. S. Conner, Jr., has been elected alternate interne to the Good Samaritan Hospital.

#### PENNSYLVANIA.

##### Philadelphia.

**The Rush Hospital for the Treatment of Consumption and Allied Diseases** has opened a country branch at Malvern.

**Club House for Medics.**—The Intercollegiate Committee of the Y. M. C. A. proposes to provide a clubhouse for the students of the medical and other professional colleges. The new clubhouse will be centrally located, will furnish a home for a few students and restaurant privileges for many. It will serve as a rendezvous for students and will have reading rooms, parlors and all other conveniences of the well-appointed clubhouse.

**Woman's Medical College Faculty Changes.**—Dr. Anna E. Broomall, because of advanced age and the pressure of private practice, has resigned from the head of the department of obstetrics in the Woman's Medical College. Dr. Broomall has occupied the chair of obstetrics since 1878. Dr. Ella B. Everitt, resident physician of the hospital, has been elected to the chair of gynecology, made vacant by the resignation of Dr. Hannah T. Croasdale.

**Jewish Hospital Additions.**—In the presence of a great throng, June 1, cornerstones of the Loeb Operating Building and of the Guggenheim Private Hospital, additions to the Jewish Hospital, were laid. Announcement was made of the donation of a sum not to exceed \$20,000 by Mrs. Sarah Eisner of Philadelphia, for erecting and equipping the Eisner Building for Nurses.

**Jefferson Commencement.**—The seventy-seventh annual commencement of the Jefferson Medical College occurred, May 29. One hundred and forty were graduated, 73 of whom were from Pennsylvania. Twenty-four prizes were awarded. The honorary degree of doctor of science was conferred upon Dr. Charles Finlay, Havana, Cuba, an alumnus, in recognition of his contributions to the science of medicine, with reference to the causation of yellow fever. A masterly address by the Hon. Charles Emory Smith completed the exercises.

#### GENERAL.

**Fourth of July Tetanus Coming.**—Physicians have begun to warn the public through the newspapers of the outbreak of tetanus that each year follows the use of the toy pistol by the small boy in his annual jubulations.

**Physicians Wanted for Philippines.**—The Civil Service Boards will hold examinations at Washington, D. C., San Francisco and other cities, June 17 and 18, for positions in the Army Medical Service in the Philippines. Applicants may address the U. S. Civil Service Commission, Washington, D. C.

**Health of Havana, Cuba.**—On May 9, 1902, Major W. C. Gorgas, surgeon, U. S. Army, chief sanitary officer of the City of Havana, submitted his report for April, 1902, as representing the sanitary conditions of the city as it passed out of the hands of the military government. In April, 1902, there were 499 deaths, equal to an annual rate of 21.77. This rate is an improvement on that of any previous April. The total number of deaths for the year 1898 was 21,252, giving a death rate of 91.53; for 1899 the total number of deaths was 8153, a rate of 33.67; for 1900, 6102 deaths, a rate of 24.40; for 1901, 5720, a rate of 22.11. For the first four months of 1902, there have been 1896 deaths, which would give for the year 5688 deaths, a rate of 20.68. This indicates very forcibly the steadily improving sanitary conditions. The streets in every direction are kept in beautiful order by the Engineer Department; but the work which the Sanitary Department has urged forward more particularly is the cleaning of the interior of the houses. The constant inspections and fines, where necessary, carried on for the past three years, have caused people generally to keep their yards and houses clean. Permanent conditions have not changed; every house in Havana still has a cess-pool, located somewhere on its premises, and it has not been the policy of the department to interfere with these conditions until the sewer system has been put in. Indeed, it would be impossible to do away with the cess-pool until the city is properly sewered. But such cleanliness as can be brought about by sweeping, washing and manual labor, is general. No case of yellow fever occurred during the month; the last case occurred in September, 1901. Only one case of smallpox was reported, the first since July, 1900, and this was a case which developed three days after the arrival of the patient from New York. Fortunately, it was discovered early and was at once sent to Las Animas Hospital for treatment. The amount of work being done for the destruction of mosquitoes is undiminished, and this has had a great effect in decreasing malaria. For the year 1900, the year previous to mosquito work, there were 344 deaths from this disease; during the year 1901, the first year of mosquito work, there were 151 deaths; for the first four months of the present year, 26 deaths.

#### Smallpox.

**Indiana:** The chief scenes of interest the past week in connection with smallpox have been in Indiana and Kentucky. The quarantine of the latter state against the former has been suspended and will probably not be resumed, owing to the agreement of Indiana to co-operate in measures to restrict the disease.

**Wisconsin:** Racine's pesthouse is full and the disease is spreading. There are 14 new cases reported. The public library has been closed indefinitely to prevent contagion by books.

#### CANADA.

**Complaints Re Quarantine at Grosse Isle.**—The second sa-loon passengers arriving by the Allan Line R. M. S. *Ionian*, have entered a complaint to the Department of Agriculture at Ottawa regarding the treatment received by them owing to

having been quarantined, on account of smallpox on board, when landed, in sheds which they state are unfit for human habitation.

**Montreal Foundling Hospital.**—The report of the medical superintendent of the Montreal Foundling Hospital for the past official year shows that there were 32 babies in the institution May 15, 1901, and that there had since been admitted 159, making a total of 191 for the year, an increase of 22 over the previous year. The receipts for the year amounted to \$6538; the expenditures, \$4779.

**The Health of Montreal.**—The hygienic committee of Montreal has just had prepared some interesting vital statistics for that city. There were 6990 vaccinations reported in 1900, only 48 of which were performed by the family physician, the balance being performed by the public vaccinators. Of this number 2094 were primary vaccinations, the balance being re-vaccinations. Contagious diseases numbered 2802, divided as follows: Diphtheria, 523; scarlet fever, 1107; typhoid, 647; smallpox, 24. The births numbered 9892; marriages 2240. Still births and deaths among illegitimate and prematurely-born children, 742; premature births, legitimates, 300; premature births, illegitimates, 31; still births, legitimates, 322; still births, illegitimates, 44. Among the French-Canadians the deaths numbered 5287, of which number 3299 were under five years of age. Among the other Catholics, 444 were under five years of age. Among the Protestants, the number was 370.

**An Insurance Case.**—Duncombe vs. the Mutual Life Insurance Company of New York was the title of an action brought by Mrs. Duncombe of St. Thomas, Ont., widow of the late Dr. Truman Duncombe, for \$5000, payment of the insurance having been refused on the ground of fraud. Dr. Duncombe, forty years of age, was an examiner for the above-mentioned company and held a number of policies in said company. On July 11, 1901, he made application for \$5000 on his own life. He made out the examination sheet himself and had a brother practitioner sign it who was not an examiner for the said company, but who had previously passed Dr. Duncombe for another company. Dr. Duncombe died suddenly Oct. 2, 1901, and, although the company paid all the other claims, they refused to pay this latter one for the reason above mentioned; hence the suit to recover. It was shown at the trial that Dr. Duncombe was not examined by his confrère on the date mentioned in the examination form. Medical experts considered that Dr. Duncombe had died of aneurism, although there was no autopsy. The undertaker who prepared the body noticed a swelling three-quarters of an inch to the left of the lower part of the sternum. He raised a fold of the abdominal wall, half-way between the sternum and umbilicus, and thrust the point of a long treacur through it, passed it eight inches upwards and toward the left arm-pit and drew off one and three-quarter pints of dark red blood, which was clear and clotted in the bottle. As this came away the swelling disappeared. The case was dismissed against the company with costs.

**Personals.**—Dr. Edgar has resigned from the superintendency of the Hamilton (Ont.) General Hospital.—Dr. Ernest Hall, Victoria, B. C., is supervising the erection of a sanitarium for consumptives at Vancouver.—Dr. Porter of North Bay, Ont., a patient at the Oakville Sanitarium for Inebriates and Morphonians, was accidentally drowned while bathing in Lake Ontario on May 6.—Dr. J. R. Cox, general secretary of the McGill Y. M. C. A., has resigned to commence the practice of medicine.—Dr. Harris, of the consulting staff of the Royal Infirmary, Manchester, is making a tour of inspection of Canadian and American hospitals for the purpose of acquiring information for use in designing and constructing the new building shortly to be erected for the institution he represents.—Dr. W. A. Young, business manager of the *Canadian Journal of Medicine and Surgery* will attend the coming meeting of the American Medical Association.—Dr. Charles P. Johns, Kingston, Ont., has been appointed assistant medical superintendent of the Pancras Infirmary in London, Eng.—Dr. H. A. Beatty, Toronto, who has declined a surgical registrarship at the Westminster Hospital, London, Eng., has been appointed chief surgeon of the Ontario division of the Canadian Pacific Railway; the same order appoints Dr. Edward W. Spragge, chief medical officer of the Ontario division.—Dr. G. P. Girdwood has retired from the chair of chemistry in the medical faculty of McGill University. He has been appointed an emeritus professor in the faculty of medicine. Dr. Girdwood was appointed professor of practical chemistry in 1872 and of chemistry in 1879.—Dr. Henderson, senior demonstrator in the

MacDonald chemistry building of McGill University, has resigned and will be succeeded by Mr. A. Douglas MacIntosh, B.Sc. (Dalhousie). M.A. (Cornell).

### FOREIGN.

**Low Mortality in 1901.**—The year 1901 has passed into history as the record year of low mortality throughout the world generally, says the commissioner of health of Chicago.

**Kaiser Forbids Eddyism.**—The German emperor has announced that any member of the German army, court, state or church who shall be led away from the path of rectitude by Eddyism shall be removed from office and ostracized.

**Japan Grows Camphor.**—The Japanese government has endeavored to control the camphor trade for increased revenue. The islands of Formosa and Hondo, the latter being the main island of Japan, are almost the sole producers of the gum. The output has been increased and efforts are being made to complete the control of the production by the government.

### LONDON LETTER.

#### New Operation Department at the London Hospital.

A new operation department, which embodies all the most recent advances which science could suggest, has been opened at the London Hospital. It consists of a theater, four operating rooms, 3 anesthetizing rooms, all facing north with large windows and top lights, four recovery rooms, five operation wards, two sisters' rooms, nurses' room, waiting room, theater superintendent's room, two attendants' rooms, instrument and sterilizing room, surgeons' room, two examining rooms, lavatory and dressers' lavatory. The operating theater has a marble gallery for students, with teak seats and gun-metal rails. A sink room is provided under the gallery. The floors of the rooms are in marble mosaic, and the walls and ceilings are lined with opalite. All angles are rounded, the doors are of polished oak with swing hinges. Separate entrances and exits are provided for each operating room and for the theater. Each day's water supply is boiled and cooled in a special apparatus. In the sterilizing room there is a steam disinfecter for dressings, coats, etc. The air-supply is led to the basement from the gardens by a glazed tunnel. It is then driven by an electric fan through a canvas water screen and cotton-wool filters. Then it passes into a heating chamber. Warm and cold air are conveyed by separate tubes. The temperature and air supply of the rooms can be controlled by levers. The usual electric fittings are installed.

#### Pathology of Pernicious Anemia.

Dr. William Hunter, whose work on this subject is so well known, communicated a paper to the Pathological Society on the "Infective Lesions of the Tongue, Stomach and Intestines in Pernicious Anemia," which was an extension of previous researches. He pointed out that in pernicious anemia there is hemolysis, which is not found in other anemias, such as those due to poverty, ulcer of the stomach, ankylostomiasis, hemorrhages, etc. Sepsis alone is incapable of producing pernicious anemia, for in septic anemia there is no evidence of hemolysis in the liver. The present communication was based on the examination of 25 cases recently observed. In seven necropsies were performed and 1145 sections and 250 cultures had been made. A peculiar form of glossitis was found in all the twenty-five cases. There was thinning of the mucosa, which in places was quite wanting so that the lymphatics of the tongue were practically in communication with the buccal cavity. This thinning of the mucosa produced a glossy condition of the surface of the tongue, which was quite peculiar to the disease. From the lymphatics of the tongue pure cultures of the streptococcus longus were obtained. Injected into mice they were fatal in six or seven days. In the stomach an inflammatory condition of the mucous membrane extending down to the mucosa was found. The epithelium was thrown off in large quantity as mucoid vomit and in the final stage complete atrophy of the gastric mucosa occurred. Marked lesions of the intestines were also found. Mucoid fluid was vomited in the mornings, which contained pure cultures of the streptococcus longus.

#### Joint Lesion in Hemophilia.

Mr. A. Lucas showed a specimen of this rare condition. A hemophilic boy had repeated hemorrhages into the knee-joints, more frequently into the right joint. This joint was much enlarged, the synovial membrane was thickened, the fringes were hypertrophied and stained from repeated hemorrhages, and the ends of the bones appeared to be enlarged. The cartilages were slightly lipped as in osteo-arthritis. The articular surface

showed many irregular pits where the cartilage had entirely disappeared.

#### Acute Pyelitis in Infancy.

At the Edinburgh Obstetrical Society, Dr. John Thomson described 8 cases observed since Dr. Emmet Holt of New York wrote his paper in 1894. The condition, therefore, is not rare. Undiagnosed it is an alarming illness, but under proper treatment it was very curable. Dr. Thomson's patients were all girls of ages varying from 7½ to 20 months, but the disease occurs not uncommonly in older children. In almost all the published cases the patients have been girls. In one of the eight cases the parents were rheumatic and in another there was a family history of gout. In six cases the previous health had been excellent, and in two there were chronic dyspepsia and rickets. The patients had all been artificially fed. Two had shown symptoms of infantile scurvy and two had had influenza. In all but one there had been troublesome constipation and in some occasional diarrhea. In five cases at least there was a history either of soreness about the anus or pain during defecation or blood had been seen in the motions, and in two there was soreness of the vulva. The symptoms were ushered in by pyrexia; in four cases there were rigors. The temperature was frequently above 104 and was of more or less remittent type so that the chart looked like that of typhoid fever. There might be screaming fits as in colic. Tenderness of the kidney was distinct in two cases. Albumin was always present in the urine, but never in greater quantity than could have been accounted for by the pus cells. Pus was always present in considerable amount. Sometimes the urine was turbid with it. Bacteria were visible in large numbers in the freshly-passed urine and cultures of the urine gave pure growths of the bacillus coli communis. This organism was the cause of the disease; it might reach the renal pelvis by the blood or by the urethra. The great preponderance of females suggested the latter. The diagnosis depends on the presence of pus and bacilli in acid urine, the occurrence of rigors (almost conclusive), local tenderness and considerable fever. Under treatment improvement was rapid, but pus did not disappear from the urine for several weeks. The essential point is to render the urine neutral. Most striking results were obtained from administration of alkalies. Citrate of potash should be freely given; 24 gr. in the twenty-four hours may suffice in mild cases, but generally 36 to 48 gr. are necessary. Relapse may occur when the potash was discontinued. Antiseptics alone are not very efficacious, but in combination with alkalies are helpful.

## Correspondence.

### A Voluntary National Examining Board.

PHILADELPHIA, MAY 31, 1902.

*To the Editor:*—There being a little misconception as to the exact purpose of a Voluntary National Board of Examiners, which I advocated at the April meeting of the Committee on National Legislation representing the American Medical Association, in the city of Washington, I will explain the plan more fully.

Some have thought that such a board could only benefit recent graduates, and that it fails to give relief to practitioners. Good as it is for the recent graduates, it is much better and was really more intended to aid and benefit practitioners, who from ill health, on account of consultation practice, professorial calls, or any cause whatsoever, may wish a license in another state. My own experience upon removal to Pennsylvania has caused me to work at the problem of reciprocity for the past three years, and I have constantly agitated the subject as a member of the Committee on National Legislation. The president and other members of the Pennsylvania State Board were anxious to exempt me from examination and tender a complimentary license, but, after consultation, found such a course impracticable. The law is mandatory and not at all elastic. All candidates for license must submit to an examination in certain branches, and *each branch is specifically named*. Although I had limited my work to general surgery for years before moving to Philadelphia, and intended doing so in this city, I was examined in obstetrics, hygiene, physiology, chemistry; in fact, all of the branches, just as a neophyte. While the board was compelled to insist that I comply with the forms of law, they were most courteous and kind to me, doing all in their power, and I would not

have any one think me antagonistic to state boards. On the contrary, it is my belief that they have done more than all other influences combined to elevate and make possible the present high standard of medical education. I feel, and have said on many former occasions, that every teacher in this country does better work now than he did before there were state boards to examine the candidates whose diplomas he signed. Recognizing the good work done by state boards, and believing them to be capable of doing even better work in the future, I would like to see a member of this Voluntary National Board a representative of the National Confederation of State Medical Examining and Licensing Boards. A national board, such as I advocate, could have discretionary power, giving a practitioner a practical and largely clinical examination. In case one is recognized as a specialist, and has limited his practice to such specialty for years, and means to do so in the future, I cannot see any good reason for exacting of him an examination in general medicine and surgery.

The plan for a national board was fully discussed, unanimously endorsed and recommended to the House of Delegates at the Saratoga meeting by the Committee on National Legislation and the representatives of the various states meeting with it.

The plan is as follows: The board is to consist of seven members, namely, the surgeons-general of the Army, Navy and Marine Hospital Service and four equally representative civil practitioners; two to be elected by the House of Delegates of the American Medical Association, one by the American Congress of Physicians and Surgeons and one by the National Confederation of State Medical Examining and Licensing Boards. In my first communication I said that a seventh might be added; I now say should, because I am convinced that it will strengthen the National board to have one of its members a representative of the National Confederation of State Medical Examining and Licensing Boards. The National and state boards would thus walk hand in hand, and the representative of the former board could report annually at the meeting of the state boards the character of the work that was being done by the central body. Confidence would necessarily follow, and such a board would at once have the support of the profession, as it would be comprised of able men absolutely above suspicion.

The time of meeting should be from June 1 to July 1, so as to accommodate the greatest number of graduates of all schools. The examination should be both theoretical and practical. Applicants should be taken into the wards of hospitals and be given opportunities to make diagnoses, examine urine, sputum and blood, as well as to outline courses of treatment. The examination should be so comprehensive as to be at least equal, if not superior, to that required by any state.

A different time and place might, if thought best, be decided upon for the examination of practitioners. Certainly abundant clinical material and cadavers would be needed, and the board would go where it could be best accommodated, and also be accessible to the greatest number of applicants. These examinations should be almost entirely practical and clinical, supplemented, if need be, by operative work upon the cadaver. It is both unnecessary and unfair to examine men of experience and merit upon such branches as chemistry, physiology, histology, etc. Such a board could have discretionary power and give the kind of examination necessary to ascertain if the applicant is competent to practice general medicine and surgery, or even a specialty, if one is recognized as a specialist. Is it fair to expect an ophthalmologist to submit to an examination in obstetrics? Yet, under the state laws, no exception can be made in his favor. Many state laws, the majority perhaps, recognize the right of one board to accept the license of another whose standard in every way equals its own. Herein is the trouble; the standards of fifty states and territories vary so widely—no two of them being alike—that a state with a high standard finds it safer to recognize no other state, for by this course embarrassments are avoided. All can, however, agree to recognize a central National board, just as all now recognize the commissions of medical officers of the Army, Navy and Marine-Hospital Service. Therefore, it points out a path to reciprocity that all may follow, and is the only attainable method, based as it is upon equity. As it is now, reciprocity can only be based upon geographical, political and

financial considerations. Intellectual qualifications alone should govern.

The board should meet, as a rule, in Washington, provided its hospital facilities are both adequate and available. It is desirable, however, to vary the place of meeting from time to time so as to make the board truly a National one in fact as well as in name, thereby subserving the interests of the greatest number of applicants. There is no doubt that the medical schools and hospitals in any of our large cities would furnish quarters and facilities for conducting the examinations with the least possible friction. I have been surprised that one gentleman took exception to my plan because he thought that all examinations were to be held in Washington. The headquarters of the board should certainly be at the National capitol, as at least three of the members will reside there and a fourth—constituting a majority—should be selected within a reasonable distance of Washington, so that if necessary he could at once join his colleagues for consultation. If the bureau of health is established by this Congress, which seems reasonably certain, I have it from an authoritative source that quarters and every facility for conducting the examinations, etc., would be furnished the board.

The fee should be \$25 for the first year, the same to be reduced when the number of applicants justifies it, which, I take it, would be the second or third year. I should like to see it not more than \$10. The expenses of the board have to be met and some fee will be necessary.

The inducement to recent graduates to take such an examination would be to obtain a diploma which should be recognized by all states and territories, so that its possessor could be allowed, like the Constitution, to follow the flag, and practice medicine and surgery anywhere within our domains. There would be other inducements: there are many positions within the gift of the Federal Government, such as contract surgeons in the Army, Navy and Marine Hospital Service, physicians to Indian agencies, and members of pension boards of examiners in all parts of the country requiring the services of more than average men. Any one holding the diploma or certificate of such a National board would at once have the advantage over any one less fortunate. In truth, in nearly all such cases a further examination could, with perfect justice to the government, be waived. So manifest are its advantages that each year there would undoubtedly be a larger number of applicants, and in time sub-boards would be necessary to accommodate the number applying, each to meet in some large city with abundant hospital facilities and accessible to many applicants. Perhaps it would be better to have more frequent sittings of one board rather than several sub-boards. Experience will determine.

A voluntary board is better for the profession than a compulsory one, even were the latter possible—which, under our form of government, is not the case—for its standard can reasonably be made higher and its certificate be a diploma *cum laude*. Letters read at the conference, before referred to, from prominent senators and representatives convinced all who were present of the impossibility of a compulsory National board. I had been so convinced before, as I had written to and talked the matter over with several of my friends in both the House and Senate. Should the fees be insufficient to secure and retain the services of the best men, the American Medical Association, the Congress of Physicians and Surgeons and the National Confederation of Examiners should add a sufficient honorarium to their appointees. The representatives of the Army, Navy and Marine Hospital Service would be estopped from accepting compensation, but, of course, their expenses would be paid.

All practitioners wishing to change their location or receive license to practice in other states would prefer appearing before the voluntary National board, and nearly all would make it convenient to do so. Of recent graduates there would be an increasing number applying from year to year, as it would soon become apparent to them that their best interests were subserved by doing so.

I have little doubt, however, that the fees would be sufficient to pay the expenses even the first year. If the examination should be held in Washington, it would be very accessible to all eastern schools, representing, we will say, a thousand

graduates. There will be more, as Philadelphia alone has each year about 400. The eastern schools are of such a standard that they would encourage their graduates to go before the voluntary National board, and it would be safe to count upon 10 per cent. (100) of the graduates of Washington, Baltimore, Philadelphia, New York, Richmond and Charlottesville (University of Virginia) and other cities adjacent to the capitol doing so. Twenty-five hundred dollars should thus be assured; the expenses would be nominal and all over and above expenses would be divided between the four examiners. This 10 per cent. could be probably doubled by the board meeting in Washington one week, and then spending a week in each of the large cities adjacent to it, viz.: Baltimore, Philadelphia and New York. The medical schools in these cities would willingly furnish quarters and facilities for conducting the examinations, and the hospitals furnish all necessary clinical advantages.

An objection which might, and will be raised, is that the surgeons-general of the Army, Navy and Marine Hospital Service cannot leave Washington, and perhaps would not be able to discharge the duties even when the sittings of the board were at the capitol. General Wyman and Admiral Rixey are very much in sympathy with the plan, will serve if they can, and if not, will detail the best man in their respective services. It is a great thing to have the moral support of our three representative medical services in any medical matter. General Sternberg, I know, retires June 8, before the Association meets. I was assured by those in authority in his office, however, that there was no doubt that his successor, whoever he may be, would do everything in his power to co-operate with the other surgeons-general and the profession in so important a matter.

This plan has been unanimously endorsed by the delegates from the several states meeting with the Committee on National Legislation, and will be recommended to the House of Delegates at the coming meeting of the American Medical Association. It is hoped that it will be carefully considered, and either it or a better plan at once inaugurated; as something should be done to encourage both a reasonable reciprocity for practitioners and a higher and a better medical education for those entering the profession, and to give in return something in the way of privileges and professional standing to those possessing it.

WILLIAM L. RODMAN.

Professor of Surgery and Clinical Surgery in the Medical-Chirurgical College of Philadelphia, and Professor of Surgery and Clinical Surgery in the Woman's Medical College of Pennsylvania.

1626 Spruce Street.

#### A Voluntary National Examining Board.

*To the Editor:*—The letters which have recently appeared in THE JOURNAL suggest two things: first, the necessity of some authority which shall have power to determine who are worthy of license to practice medicine in this country and, second, in whom shall that authority be vested. This naturally leads to the inquiry: By what means can that authority be enforced? Clearly such power can only be obtained through National legislation. In order to obtain that, the scheme must be of such a character as to commend itself to the House of Representatives and the Senate, and finally the President. As has been suggested by one correspondent, the right of the citizen of this country to earn his living is a constitutional one with which Congress will be slow to meddle, the greatest care being always observed to keep within constitutional limits, and the attempt to place the rights and liberties of, say 300,000, educated and honorable physicians in the hands of a small, irresponsible body of men, as suggested by Dr. Rodman, would be in such direct controvention of their rights as to preclude the enactment of such a law. In fact, much of the state legislation in this regard would scarcely stand an appeal to the Supreme Court of the United States.

A large representative body might be formed, composed of men appointed by the legislatures of each and all the states, say two from each state, in whom the government might have enough confidence to entrust them with such great powers and responsibilities, and even then the graduates of the great

universities and colleges would have to be protected, as all these powerful bodies would have their interests to preserve, and would take care to preserve them. Having had much legislative experience I speak with some confidence on this point.

If we had a great national college, like the Royal College of England, the entrance to which might be carefully guarded, whose members would be entitled to practice anywhere in this realm, it might be sanctioned by the government and would answer the ends sought by those who are advocating a change. Let me suggest that the needed legislation should be strongly felt and clearly understood before steps are taken to secure it. The present state boards of examination should be set aside in favor of a national body, as I have already described, and they should be compelled to accept diplomas of the three-year teaching colleges without dispute as a right to membership, and details as to state examinations could easily be arranged.

Yours, etc.,

ADAM E. FORD, M.D.

[Our correspondent does not seem to appreciate the fact that what he advocates would be unconstitutional, and that the board advocated by Dr. Rodman is purely a voluntary one, and no one would be forced to go before it.—Ed.]

#### Reciprocity in Medical Licensure.

BURLINGTON, IOWA, May 31, 1902.

*To the Editor:*—In all that I have seen written (and I have seen a good deal) in the medical journals to which I have access, about "reciprocity in medical licensure," I fail to note the one simple solution of the question, namely: An amendment to the medical law, in each of the several states having medical practice laws, which shall provide that the penalties shall not attach to those legally qualified to practice in other states. Heaven knows there are already exemptions in plenty and far more dangerous than this would be; and there is scarcely a chance for such an amendment to fail in any legislative body. But what a spectacle for the masses it is, to see so much remonstrance about the exact administration of the laws we have fought so valiantly to have enacted! For myself I want to say, that while I believe a good medical practice law is a benefit alike to the public and the medical man, I am not enthusiastic over any of those with which I am familiar. Drawn up, as the Iowa law was, by a combination with the Homeopaths and Eclectics—with whom under no other circumstances could we associate—they bear the stamp of insincerity; and naturally fail to win the respect of the public and the courts.

Truly yours,

H. B. YOUNG.

#### Married.

BERNARD S. FRENCH, M.D., Whitefield, N. H., to Miss Elsie L. Berry of Baltimore, May 21.

GEORGE LENZ, M.D., Gloversville, N. Y., to Miss Annie Grant of Ingersoll, Ontario, May 21.

FRANK B. WHITMORE, M.D., to Miss Anna B. Washburn, both of West Union, Iowa, May 20.

CHARLES GIVEN FOOTE, M.D., Cleveland, Ohio, to Miss Kittie A. Richards of Chicago, May 24.

GUSTAVUS A. HEINRICH, M.D., to Miss Anna L. Neurnberger, both of New Athens, Ill., May 18.

JOHN E. PRATHER, M.D., Glasgow, Ill., to Miss Katherine B. Cumby of Winchester, Ill., May 21.

MILES D. CHISHOLM, M.D., Westfield, Mass., to Miss Margaret A. Rison, of Williamsburg, Va., May 21.

ALBERT F. CONREY, M.D., Baltimore, to Miss Katherine Bradford of Portsmouth, Va., at Baltimore, May 21.

OLE H. BAKKE, M.D., Blooming Prairie, Minn., to Miss Mabel A. Fjeldstad, of South Minneapolis, Minn., May 21.

SAMUEL STEVENS, M.D., Dowagiac, Mich., to Miss Lillian Roosevelt of Benton Harbor, Mich., at South Bend, Ind., May 21.

## Deaths and Obituaries.

## Dr. William Miller Ord.

Death has removed one of the most celebrated of the London medical teachers, Dr. Ord, consulting physician to St. Thomas' Hospital. His health had been failing since an attack of influenza three years ago. Two years ago he relinquished all active work and retired to the country. Dr. Ord graduated at the London University in 1857, and had a most distinguished career. In 1869 he became a member of the College of Physicians, and two years later assistant physician to St. Thomas' Hospital. His marked ability and energy led to his appointment as lecturer in physiology in succession to the celebrated Dr. Murchison. He was a teacher of extraordinary ability, and as a writer he gave much valuable work to the medical world. In medicine his most important original contribution was the working out of the pathology and symptomatology of myxedema, the name of which he invented.

**William Hamilton Watkins, M.D.** Tulane University, New Orleans, 1868, a prominent physician of New Orleans, and widely known as an authority on yellow fever, died from cancer of the stomach at the home of his wife's mother in Milwaukee, May 23, after an illness of two years, aged 54. He was chief medical inspector of the New Orleans Sanitary Association, chief inspector of the New Orleans Board of Health, editor of the *New Orleans Medical and Surgical Journal* and chairman of the Yellow Fever Board during the epidemic of 1897.

**Matthias Abell, M.D.** College of Physicians and Surgeons, New York, 1857, a member of the Rhode Island Medical Society and an honorary member of the New Jersey State Medical Society, died, May 1, at his residence in Providence, R. I., aged 71.

**Grant G. Cox, M.D.** Hospital College of Medicine, Louisville, Ky., 1898, a practitioner of Boothsville, W. Va., who was injured in a runaway accident at Watson, May 13, died at Cook's Hospital, Parkersburg, as a result of his injuries, May 23.

**Green B. Battle, M.D.** Medical College of Georgia, Augusta, 1875, a son of the late Dr. T. W. Battle of Columbus, Ga., a practitioner of Lumpkin, Ga., died at the home of his mother in Columbus, after a prolonged illness, aged 49.

**Eleazer A. Pyatt, M.D.** Jefferson Medical College, Philadelphia, 1861, for more than thirty years a resident of Bethany, Ill., died at his home in that place, May 19, from dysentery, after an illness of four weeks, aged 69.

**John Vedder, M.D.** College of Physicians and Surgeons of the Western District of New York, Fairfield, 1838, president of the New York State Anti-Vivisection Society, died at his home in Saugerties, N. Y., May 22, aged 86.

**Warren Parsons, M.D.** National Medical College, Washington, D. C., 1842, a retired physician of Rye, N. H., who had practiced in that town for sixty years, died May 20, aged 83.

**Henry Van den Berg, M.D.** Keokuk Medical College, 1883, a practitioner of Fremont Center, Mich., died at Zeeland, Mich., May 23, after an illness of one year, aged 45.

**James K. Nevin, M.D.** Rush Medical College, Chicago, 1887, died at his home in Ironwood, Mich., May 18, from pneumonia, after an illness of a week, aged 47.

**John B. Wilson, M.D.** Kentucky School of Medicine, Louisville, 1888, a physician of Mount Vernon, Ind., died, May 20, at Denver, where he had gone for his health.

**Henry Howard Hill, M.D.** Jefferson Medical College, Philadelphia, 1867, medical inspector of Bedford County, died at his home in Everett, Pa., May 22, aged 57.

**P. H. McGurty, M.D.** Kentucky School of Medicine, Louisville, 1892, died from consumption, May 21, at the home of his sister in Charleston, Ill.

**Edward Bernier, M.D.** Dartmouth Medical College, Hanover, N. H., 1889, died at his home in Schaffer, Mich., May 19, from heart disease.

**Joseph F. McCloughan, M.D.** University of Pennsylvania, Philadelphia, 1871, died at his home in Swartswood, N. J., May 16, aged 53.

**Alexander Montague, M.D.** New York University, 1868, for many years a practitioner of Galt, Cal., died in Sacramento, May 21.

**George W. Archer, M.D.** Medical College of Virginia, Richmond, 1887, died at his home in Detroit, Mich., May 18.

**Ford S. Dodds, M.D.** Western Reserve University, Cleveland, 1868, died at his home in Anna, Ill., May 21.

## Association News.

## A Suggestion as to Exhibits.

It is suggested in cases of papers to be read in any section, in connection with which specimens are exhibited, that the authors send the latter to the pathologic exhibit. This course will enable a better inspection and study and consequently add to the usefulness of their communication. The specimens can be put in the hands of the Committee on the Pathologic Exhibit, of which Dr. F. M. Jeffries, Saratoga, N. Y., is chairman, and can be taken out for presentation to the section when the paper is read. The utility of the suggestion is obvious and needs no further comment.

## Proposed Amendments.

The following amendments are to be acted on by the House of Delegates at the next annual meeting of the American Medical Association:

Amendment to the Constitution and By-laws, offered by Dr. L. B. Tuckerman, of Ohio: Amend Section 3, Chapter VII of the By-laws by substituting the following:

"Section 3. Committee on Legislation. The Committee on Legislation shall consist of three members appointed by the President of the Association for a term of three years. One member shall be a resident of Washington, D. C., one of Baltimore, and one of Philadelphia. It shall be the duty of the Committee to represent before Congress the wishes of this Association regarding any proposed legislation that in any respect bears upon the promotion and preservation of the public health or upon the material or moral welfare of the medical profession. This Committee shall also invite to a conference once a year, or oftener if need be, one delegate each from the medical service of the United States Army, the United States Navy, and the Marine-Hospital Service, one from the Bureau of Animal Industry, and one from each affiliated state or territorial medical society: such conference to meet in Washington to consider questions of medical and sanitary legislation, and to report back to this Association and to the several state and territorial societies."

Amendment to the Constitution and By-laws, offered by Dr. T. J. Happel, of Tennessee:

Chapter IX, Section 7, as follows: Strike out the following words of Section 7, Chapter IX, "reprints and transactions of Sections, including its lists of members, its rules of order, its lists of officers, as now published, shall be paid for out of the funds of the Association, and furnished free to members of the Association."

## Representatives from State Societies to the House of Delegates of the American Medical Association.

The following have been officially certified to the Secretary as representatives:

Alabama—W. H. Sanders, Mobile; W. M. Wilkerson, Montgomery.

Arizona—W. H. Ward, Phoenix.

Arkansas—J. A. Dibrell, Little Rock.

California—H. Bert Ellis, Los Angeles.

Colorado—C. K. Fleming, Denver.

Connecticut—

Delaware—Willard Springer, Wilmington.

District of Columbia—George M. Koerber, Washington.

Florida—R. D. Murray, Key West.

Georgia—James B. Morgan, Augusta; Floyd W. McRae, Atlanta.

Idaho—Ed. E. Maxey, Boise.

Illinois—John T. McAnally, Carbondale; F. X. Walls, Chicago; O. B. Will, Peoria.

Indian Territory—

Indiana—G. W. H. Kemper, Muncie; Edwin Walker, Evansville; William N. Wishard, Indianapolis; D. C. Peyton, Jeffersonville.

Iowa—George F. Jenkins, Keokuk; J. R. Guthrie, Dubuque.

Kansas—J. E. Minney, Topeka.

Kentucky—J. N. McCormack, Bowling Green; Thomas Hunt Stucky, Louisville.

Louisiana—

Maine—Seth C. Gordou, Portland.

Maryland—William H. Welch, Baltimore; William Oster, Baltimore.

Massachusetts—W. T. Councilman, Boston; H. E. Marion, Brighton; J. Collins Warren, Boston; F. C. Shattuck, Boston; C. H. Williams, Boston; J. F. A. Adams, Pittsfield.

Michigan—H. O. Walker, Detroit; V. C. Vaughan, Ann Arbor.

Minnesota—A. W. Abbott, Minneapolis.

Mississippi—J. C. Hall, Anguilla.

Missouri—Frank J. Lutz, St. Louis.

Montana—

Nebraska—H. M. McClanahan, Omaha.  
 New Hampshire—Ira J. Prouty, Keene.  
 New Jersey—E. J. Marsh, Paterson; Chas. J. Kipp, Newark;  
 Luther M. Halsey, Williamstown.  
 New Mexico—G. C. Bryan, Alamogordo.  
 New York—E. E. Harris, New York; C. A. Wall, Buffalo;  
 H. O. Arrowsmith, Brooklyn; E. D. Ferguson, Troy; Chas. E.  
 Quimby, New York.  
 Nevada—  
 North Carolina—James A. Burroughs, Asheville; H. A.  
 Royster, Raleigh.  
 North Dakota—I. N. Wear, Fargo.  
 Ohio—Charles A. L. Reed, Cincinnati; P. Maxwell Foshay,  
 Cleveland; Frank Warner, Columbus.  
 Oklahoma—  
 Oregon—Andrew C. Smith, Portland.  
 Pennsylvania—William S. Foster, Pittsburg; George W.

Wisconsin—W. T. Sarles, Sparta; J. R. Barnett, Neenah.  
 Wyoming—R. Harvey Reed, Rock Springs.  
 United States Marine-Hospital Service—Walter Wyman,  
 Washington, D. C.  
 Medical Department U. S. Army—D. M. Appel, Ft. Bay-  
 ard, N. M.  
 Medical Department U. S. Navy—R. A. Marmion, Wash-  
 ington, D. C.

#### Delegates from the Sections.

Practice of Medicine—J. M. Anders, Philadelphia; Norman  
 Bridge, Los Angeles.  
 Surgery and Anatomy—C. A. Powers, Denver; A. D. Bevan,  
 Chicago.  
 Obstetrics and Diseases of Women—L. S. McMurtry, Louis-  
 ville; W. H. Humiston, Cleveland, Ohio.  
 Hygiene and Sanitary Science—S. G. Bonney, Denver; N. S.  
 Davis, Jr., Chicago.

View of Property Recently Purchased by the Board of Trustees of the American Medical Association. (See p. 1532.)

Guthrie, Wilkesbarre; A. P. Hull, Montgomery; W. T. Bishop,  
 Harrisburg; H. S. McConnell, New Brighton; John B. Roberts,  
 Philadelphia; William M. Welch, Philadelphia; Webster B.  
 Lowman, Johnstown.

Rhode Island—John Champlin, Westerly.  
 South Carolina—  
 South Dakota—  
 Tennessee—W. Frank Glenn, Nashville.  
 Texas—H. A. West, Galveston.  
 Utah—  
 Vermont—D. C. Hawley, Burlington.  
 Virginia—J. R. Gildersleeve, Tazewell; Landon B. Edwards,  
 Richmond; Rawley W. Martin, Lynchburg.  
 Washington—Park Weed Willis, Seattle.  
 West Virginia—L. D. Wilson, Wheeling.

Ophthalmology—J. A. Lippincott, Pittsburg, Pa.; H. V.  
 Würdemann, Milwaukee.

Diseases of Children—S. W. Kelly, Cleveland, Ohio; A. C.  
 Cotton, Chicago.

Stomatology—G. V. I. Brown, Milwaukee; A. E. Baldwin,  
 Chicago.

Nervous and Mental Diseases—H. A. Tomlinson, St. Peter,  
 Minn.; H. N. Moyer, Chicago.

Cutaneous Medicine and Surgery—W. L. Baum, Chicago;  
 W. T. Corlett, Cleveland, Ohio.

Laryngology and Otology—Emil Mayer, New York City;  
 George C. Stont, Philadelphia.

Materia Medica, Pharmacy and Therapeutics—O. T. Osborne,  
 New Haven, Conn.; A. B. Lyons, Detroit, Mich.

Physiology and Pathology—W. A. Evans, Chicago; Alfred  
 Stengel, Philadelphia.

New Home for The Journal. (See p. 1532.)

**New Members.**

The following is a list of new members for the month of May, 1902:

**ALABAMA.**

Lupton, F. A., Birmingham.

**ARIZONA.**

Stone, H. H., Phoenix.

**ARKANSAS.**

Oakley, J. F., Augusta.

**CALIFORNIA.**

Gordon, S. B., Salinas.

Whiting, H. C., Santa Cruz.  
 Uttley, J. H., Los Angeles.  
 Deane, L. C., San Francisco.  
 Adam, Geo., San Francisco.  
 Edwards, T. C., Salinas.  
 Campbell, P. C., Port Richmond.  
 Cleary, Geo., San Diego.  
 Moore, M. L., Los Angeles.  
 Hart, A. C., Sacramento.

**CONNECTICUT.**

Coyle, W. J., Windsor Locks.  
 Smith, E. L., Hotchkissville.

Bull, T. W., Saugatuck.  
 Davis, E. T., Ellington.  
 Cochran, L. B., Hartford.  
 Ring, H. W., New Haven.  
 Tingley, W. K., Norwich.  
 Wheeler, F. H., New Haven.

**DISTRICT OF COLUMBIA.**

LaGarde, L. A., Soldiers' Home.

**FLORIDA.**

Hutchason, C. L., Jacksonville.

**GEORGIA.**

Johnson, G. H., Savannah.

**HAWAIIAN ISLANDS.**

Katsuki, Ichitaro, Honolulu.

**IDAHO.**

Emerson, J. W. S., Shoshon.

**ILLINOIS.**

Ballenger, W. L., Chicago.  
 Graham, H. G., Chicago.  
 Adams, Chas., Chicago.  
 Porter, J. E., Shannon.  
 McCrelight, S. L., Chicago.  
 Snow, Morton, Chicago.  
 Whitaker, W. B., Chicago.  
 Belrne, H. P., Quincy.  
 Blaine, W. C., Tuscola.  
 Crain, L. F., Dongola.

**INDIANA.**

Benham, C. W., Vincennes.

Hawes, J. K., Columbus.  
Ross, R. O., Indianapolis.

## IOWA.

Bowen, D. H., Waukon.

## KENTUCKY.

Moore, J. S., New Hope.  
Caldwell, D., Paducah.  
Hudgins, C. L., Olive Hill.  
Smith, W. E., Yost.

## LOUISIANA.

Perkins, W. M., New Orleans.

## MAINE.

Sturdivant, A. H., Augusta.

## MARYLAND.

Randolph, R. L., Baltimore.  
Naylor, N. L., Pikesville.  
Smith, W. H., Baltimore.  
Porter, M. G., Lonaconing.

## MASSACHUSETTS.

Smith, A. C., Brockton.  
Kepner, C. O., Boston.  
Richards, W., Natick.  
Haddock, C. W., Salem.  
Hallett, E. B., Worcester.  
Spencer, G. A., Haverhill.  
Hanley, J. J., Boston.

**The American Association of Life Insurance Examining Surgeons** will meet at Saratoga June 9. A very interesting program has been arranged and we mention a few extracts. Dr. Woods Hutchinson will present a résumé of his conclusions on the form of the chest in phthisis, and its significance. This will be discussed by Dr. William A. Evans, Chicago, who will report the result of his recent measurements of a large number of consumptive chests. Dr. Byron G. Van Horne, Englewood, N. J., will read a paper on "Hernia and Life Insurance," and Dr. George W. Webster, Chicago, on "The Prognosis in Organic Disease of the Heart." Dr. William A. Adams, Texas, the medical inspector in that state for the Equitable Life Assurance Society, and Dr. Charles Lyman Greene, St. Paul, the author of "Medical Examination for Life Insurance," have also promised papers.

**American Urological Association.**—The annual meeting of this Association will be held in Saratoga, June 13-14. The address of the president, Dr. Ramon Guiteras, New York, will be on "Advances in Urology." Dr. Robert T. Morris, New York, will exhibit specimens of renal calculi. The following papers are announced: "Diagnosis of Renal Tuberculosis," by Dr. John von Glahn, New York; "The Technic of Nephropexy," by Dr. Augustin H. Golet, New York; "The Knee-Chest Position for Operation on the Ureters," by Dr. Howard A. Kelly, Baltimore; "Stone in Ureter, with Report of Five Cases," by Dr. Orville Horwitz, Philadelphia; "The Importance of Separating Kidney Urines," by Dr. Andrew J. Downes, Philadelphia; "Cystoscopy in the Female," by Dr. William R. Pryor, New York; "Cystoscopy in the Male," by Dr. William K. Otis, New York; "Tuberculosis of the Bladder," by Dr. Joseph B. Bissell, New York; "Operative Indications in Prostatic Hypertrophy," by Dr. Hugh H. Young, Baltimore; "Permanent Results, Failures and Relapses Following the Bottini Operation," by Dr. Filipp Kreissl, Chicago; "A Study of Twenty-three Cases Treated by Perineal Prostatectomy," by Dr. Alexander H. Ferguson, Chicago; "The Diagnosis and Treatment of Chronic Prostatitis," by Winfield Ayres, New York; "The Diagnosis and Operative Treatment of Prostatic Hypertrophy," by Dr. Bransford Lewis, St. Louis; "Diabetes," by Dr. I. N. Love, New York; "Treatment of Uremia," by Dr. Egbert H. Grandin, New York; "Tuberculosis of the Genito-Urinary Tract," by Dr. Granville MacGowan, Los Angeles; "Outlines of Microscopic Urinalysis," by Dr. Louis Heitzman, New York; "A Sketch of the Chemistry of the Urine," by Dr. Heinrich Stern, New York; "A Case of Pregnancy Complicated with Pyonephrosis," by Dr. Charles G. Cumston, Boston; "A New Silver Salt in the Treatment of Urethritis," by Dr. George K. Swinburne, New York; and "Failures in the Irrigation Treatment of Gonorrhea," by Dr. Ferd. C. Valentine, New York.

## Societies.

## COMING MEETINGS.

American Medical Association, Saratoga Springs, N. Y., June 10 to 13.

American Association of Life Insurance Examining Surgeons, Saratoga Springs, June 9, 1902.

National Confederation State Medical Examining and Licensing Boards, Saratoga Springs, N. Y., June 9, 1902.

Association of American Medical Colleges, Saratoga Springs, N. Y., June 9, 1902.

American Climatological Association, Los Angeles, Cal., June 9-11, 1902.

American Proctological Association, Saratoga Springs, N. Y., June 10, 1902.

Medical Society of Delaware, Newark, June 10, 1902.

Massachusetts Medical Society, Boston, Mass., June 10-11, 1902.

Medical Society of the State of North Carolina, Wilmington, June 10-14, 1902.

Colorado State Medical Society, Pueblo, June 17, 1902.

American Medico-Psychological Association, Montreal, June 17-20, 1902.

Minnesota State Medical Society, Minneapolis, June 18, 1902.

Medical Society of New Jersey, Atlantic City, June 24-26, 1902.

Washington State Medical Society, Tacoma, June 24-26, 1902.

Michigan State Medical Society, Port Huron, June 26-27, 1902.

Medical Association of Nevada, Virginia City, July 7, 1902.

American Ophthalmological Society, New London, Conn., July 16, 1902.

**American Medico-Psychological Association.**—The fifty-eighth annual meeting of this Association will be held at the Windsor Hotel, Montreal, June 17 to 20, inclusive.

**Camden District (N. J.) Medical Society.**—At the fifty-sixth annual meeting of this Society, held in Camden, May 13,

## Saratoga Meetings.

Among the meetings to be held at Saratoga Springs during the week of the Association meeting are those mentioned below. Others have received previous notice in these columns.

Dr. John G. Doron, Camden, was elected president; Dr. John W. Marcy, Merchantville, vice-president; Dr. Paul M. McCray, Camden, secretary; Dr. Joel W. Fithian, Camden, treasurer; Dr. Harry H. Sherk, Camden, historian; Dr. Joseph H. Willis, Camden, reporter, and Dr. William H. Ireland, Camden, censor.

**Barnstable District (Mass.) Medical Society.**—The annual meeting of this Society was held at Hyannis, May 8, at which Dr. Edwin M. Parker, South Yarmouth, was elected president; Dr. Solomon F. Haskins, Cotuit, vice-president; Dr. James H. Higgins, Marston's Mills, secretary; Dr. Charles W. Milliken, Barnstable, treasurer; Dr. George N. Munsell, Harwich, and Dr. L. Edmonds, Harwich, commission of trials.

**Hempstead Memorial Academy of Medicine (Portsmouth, Ohio.)**—On May 5, the Academy held its annual meeting, at which Dr. D. Tod Gilliam, Columbus, read a paper on "Woman and Her Ear"; Dr. Edwin S. Ricketts, Cincinnati, delivered a eulogy on the late Dr. Arthur Titus and Dr. Daniel A. Berndt, retiring president, gave a banquet. Dr. William W. Smith was elected president; Dr. Osborne, vice-president; Dr. Milton S. Pixley, secretary, and Dr. Henri G. Halderman, treasurer.

**Middle Tennessee Medical Association.**—The sixteenth semi-annual meeting of this body was held at Lewisburg, May 15 and 16. At the evening session, the president, Dr. George W. Moody, Shelbyville, delivered an address on "The Dark and Bright Sides of the Medical Profession." Sparta was selected as the next place of meeting. Dr. Leonidas L. Sheddan, Fayetteville, was elected president, and Dr. Rufus E. Fort, Nashville, vice-president. Dr. Frank B. Reagor, Shelbyville, was re-elected secretary.

**Cecil County (Md.) Medical Society.**—The annual meeting of this Society was held at Elkton, May 20. An address was delivered by Dr. William H. Welch, of Baltimore, on "Infection and Immunity." Resolutions were passed on the recent death of Dr. Harry P. Hinchliffe, Elkton, secretary of the Society. The following officers were elected: President, Dr. George S. Dare, Rising Sun; vice-president, Dr. David L. Gifford, Zion; secretary, Dr. Howard Bratton, Elkton, and treasurer, Dr. John H. Jamar, Elkton.

**Indiana State Medical Society.**—The fifty-third annual meeting of this Society was held at Evansville, May 22 and 23. The convention was the largest in the history of the Society, nearly 500 being present. The delegates were welcomed to Evansville by Dr. Morton J. Compton, a member of the Council, in the absence of the Mayor. President Alenbert W. Brayton, Indianapolis, responded. Dr. Victor C. Vaughan, Ann Arbor, delivered the annual address on "Immunity, Toxins and Antitoxins; the Employment of Autitoxins in the Treatment of Disease." In the evening the guests were given a reception and a moonlight ride on the Ohio by the Vanderburg County Medical Society. The following officers were elected: Dr. John B. Berteling, South Bend, president; Dr. William H. Gilbert, Evansville, vice-president; Dr. Frederick C. Heath, Indianapolis, secretary, and Dr. Albert E. Bulson, Jr., Fort Wayne, treasurer. Richmond was selected as the next meeting-place.

**Iowa State Medical Society.**—The fifty-first annual meeting of this Society was held in Des Moines, May 21, 22 and 23, under the presidency of Dr. James R. Guthrie, Dubuque. The members were welcomed to the city by Hon. James Brenton, mayor, and Dr. Samuel Bailey responded on behalf of the Society. The pathologic exhibit was especially good. In his annual address the president recommended that there be legislation to eliminate the evil connected with the present system of expert testimony. He also advocated properly-enforced vaccination as the only means of banishing smallpox, and closed his retrospect by citing some of the things which have made American Medicine great in the last century. In the evening Mr. E. D. Salmon, Chief of the Bureau of Animal Industry, Washington, delivered an address on "Bovine and Human Tuberculosis," which was followed by a general discussion of the subject. On the second evening a complimentary concert was given at Foster's Opera House. The election of officers resulted as follows: Dr. James Taggart Priestley, Des Moines, president; Drs. William Jepson, Sioux City, and Charles F. Wahrer, Fort Madison, vice-presidents; Dr. Vernon L. Treynor, Council Bluffs, secretary; Dr. Willis W. Dean, Sioux City, assistant secretary, and Dr. William B. Small, Sioux City, treasurer. Sioux City was selected as the next place of meeting.

## OHIO STATE MEDICAL ASSOCIATION.

*Fifty-seventh Annual Meeting, held at Toledo, May 28-30, 1902.*

The President, Dr. Edmond C. Brush, in the Chair.

At the meeting over 400 members were in attendance, and the sessions were marked by unusual interest in both the scientific and business proceedings. The guests of the meeting were Dr. James Tyson, Philadelphia, who delivered the address in medicine; Dr. A. A. Ochsner, Chicago, who delivered the address in surgery, and Dr. W. J. Mayo, Rochester, Minn.

### President's Address.

President Brush spoke of the advantage of affiliating local medical societies with the state and national organizations. He conceded that the Ohio State Society had not the numerical strength it should have. Instead of 1000 members, it should have five times that number. The society had grown in 56 years from a membership of 25 to its present proportions. The increase was not in ratio with the times. The president observed that it was usually the busy doctor that attended the conventions. He found that the men who were always absent were the drones. Those with the medical society habit were the leaders in their respective spheres.

The tendency in larger cities is to have too many organizations. College cliques, hospital cliques and those who are in no clique, get together and form too many societies.

The effort to make the local society a part of the state organization so far has proved unsuccessful. This is because the doctors of smaller places do not like to mix in with strangers. They are willing to attend the local gatherings where they meet with friends and acquaintances, but they refuse to mix with the state physicians. The idea now is to get these stay-at-homes to come to the annual state meetings.

President Brush spoke cheerfully of the future of the organization and pointed with pride to the fact that the organization is now better off financially than it ever was.

### Reorganization.

The chief business to come before the session was the proposal to reorganize the body in accordance with the request of the American Medical Association. The constitution and by-laws for state societies, which was drafted by the Committee on Organization of the American Medical Association, was submitted as a report of the committee of reorganization of the state society. The consideration of this report had been made a special order for Wednesday evening, when, after some discussion, it was referred again to the same committee with some suggestions as to changes and with instructions to give a hearing to all members who wished to be heard on the question. Immediately the committee began a three-hour session at which the new organic law was considered section by section. At the close of the hearing the audience voted favorably on the proposition to adopt the new constitution. At 10 o'clock on the following morning the question came up in the general meeting for final disposition. A motion to adopt the new constitution was made, and in a large meeting, without any discussion, it was carried without a single dissenting vote.

Only three changes were made in the draft submitted by the Committee on Organization. The first provides that the vice-presidents shall be arranged in numerical order—first, second and third. The second made the annual assessment one dollar. The third was the most significant, as it involved the substitution of a new clause for Chapter X, "Rules of Conduct." As submitted, this read: "The principles set forth in the Code of Ethics of the American Medical Association shall govern the conduct of members in their relations to each other and to the public." As adopted this chapter reads: "The ethical principles governing the members of the American Medical Association shall govern the conduct of the members of this Association in their relations to each other and to the public."

### Officers.

The following officers were elected: President, Dr. William C. Chapman, Toledo; vice-presidents, Drs. George W. Crile, Cleveland; Clovis M. Taylor, Columbus; Martin Stamm, Fremont, and S. F. Covington, Bellefontaine; secretary, P. Max-

well Foshay, Cleveland; treasurer, James A. Duncan, Toledo; delegates to the American Medical Association, Charles A. L. Reed, Cincinnati; P. Maxwell Foshay, Cleveland; Frank Warner, Columbus; alternates, Edwin Ricketts, Cincinnati; T. Clarke Miller, Massillon; George Goodhue, Dayton.

The Society will meet next year in Dayton.

#### MEDICAL ASSOCIATION OF MISSOURI.

*Forty-fifth Annual Meeting, held at St. Joseph,*

*May 20-22, 1902.*

President, Jefferson Davis Griffith, Kansas City, in the Chair.

#### Welcome to St. Joseph.

At the opening session Mayor Borden welcomed the Association to St. Joseph, and Dr. William G. Moore, St. Louis, made a fitting response.

#### President's Address.

Special cars carried members of the Association to Lake Contrary where a night session was held at the Lake Casino. At this session the president delivered the annual address, in which he advocated high ideals and consecration to the work of life. He devoted some effort to showing the necessity for a reorganization of the state society on a plane which would make it more of a power in the affairs of the state. He advocated the adoption of the principles of civil service in the conduct of the affairs of the state institutions, and favored the maintenance of hospitals for epileptics, crippled and deformed children.

#### Reorganization.

The committee appointed at the meeting last year to prepare a constitution and by-laws for the society made its report. The constitution submitted provides for reorganization on the basis of the plans adopted by the American Medical Association and, after an animated discussion, was adopted.

#### Cancer a Parasitic Disease.

Dr. ROSWELL PARK, Buffalo, N. Y., delivered an address on "Some Aspects of the Cancer Problem." He went into some detail on the parasitic theory of cancer. He considers it the most important problem in pathology, and cited statistics to show the rapid increase in fatality from the disease, though much of this increase he attributed to improved diagnosis. But as far as the final solution is concerned, it is still the problem of the ages, although considerable encouragement has been derived from the investigations conducted in the Buffalo laboratories under the direct supervision of the board of health of New York.

#### Election of Officers.

The election of officers resulted as follows: President, Dr. Woodson Moss, Columbia; vice-presidents, Drs. M. P. Overholter, Harrisonville; Barton Pitts, St. Joseph; Anselm C. Robinson, St. Louis; Frank De Vilbiss, Spring Garden, and Vaughan Q. Bonham, New Franklin; recording secretary, Dr. Clarence M. Nicholson, St. Louis, and associate recording secretary, Dr. Edward J. Goodin, St. Louis. The Association will meet in Excelsior Springs, May 21-23, 1903.

#### A Home for the American Medical Association.

We print on pages 1528 and 1529 illustrations of new property recently purchased by the American Medical Association. That on page 1528 is a reproduction of a photograph of the property. It is situated on the northeast corner of Dearborn Avenue and Indiana Street, Chicago, on the north side, and quite near the business center. The property is covered with five houses, renting from \$35 to \$50 each, the two on the north—to the left—are being taken down to make room for the new building. The size of the ground is 80x100. The illustration on page 1529 is a reproduction of the architect's plans for the new building for THE JOURNAL. It will be 40x80 feet, three stories and a high basement. The basement will be occupied by the presses and folders, the first floor by the bindery and mailing room, and the second by the editorial and business offices. The front part of the third story will be occupied by the library, and the rear by the composing room. The cost of the building complete will be a little over \$30,000.

## Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

#### Seborrhea Sicca.

The following combination is recommended by J. F. Payne, in Allbutt's "Sys. of Med.," in the treatment of dandruff:

|                        |         |    |
|------------------------|---------|----|
| R. Sulph. precip. .... | gr. xv  | 1  |
| Acidi carbol. ....     | gtt. xv | 1  |
| Olei amygd. amar. .... | m. ii   | 12 |
| Paraffin moll. ....    | 3i      | 30 |

M. Ft. unguentum. Sig.: To be applied locally at night by rubbing thoroughly into the roots of the hair.

The foregoing may be continued for a fortnight when one of the following lotions may be substituted:

|                              |             |       |
|------------------------------|-------------|-------|
| R. Liq. carbon, deterg. .... | m. iv ad. x | 25-65 |
| Glycerini ....               | 3ss         | 2     |
| Aq. rosæ q. s. ad. ....      | 3i          | 30    |

M. Ft. lotio. Sig.: To be applied thoroughly to the scalp once a day; or:

|                                 |        |     |
|---------------------------------|--------|-----|
| R. Glyceriti acidi tannici .... | 3i-3ii | 4-8 |
| Acidi carbol. ....              | m. v   | 30  |
| Aq. rosæ q. s. ad. ....         | 3i     | 30  |

M. Ft. lotio. Sig.: Apply locally; or:

|                            |          |    |
|----------------------------|----------|----|
| R. Tinct. cantharidis .... | 3ss      | 2  |
| Hydrarg. bichloridi ....   | gr. i    | 06 |
| Spts. camphoræ ....        | gtt. iii | 20 |
| Aq. destil. ....           | 3i       | 30 |

M. Ft. lotio. Sig.: Apply locally with thorough friction once a day.

The last combination is of service only when there is a complete absence of inflammation.

#### Chilblains.

The following ointment is regarded as one of the best combinations in the treatment of chilblains. It is made up according to Lassar's formula:

|                       |         |    |
|-----------------------|---------|----|
| R. Acidi carbol. .... | gr. xv  | 1  |
| Olei olivæ ....       | 3iiss   | 10 |
| Ung. diachyli ....    | 3v      | 20 |
| Olei lavendulæ ....   | gtt. xv | 1  |
| Petrolati ....        | 3v      | 20 |

M. Sig.: Spread the ointment on linen and apply to the affected part with a bandage, over night.

#### As a Galactagogue.

The following combination containing calcium glycerino-phosphate has been recommended as a galactagogue:

|                                |      |    |
|--------------------------------|------|----|
| R. Calcii glycerino-phos. .... | 3i   | 4  |
| Tinct. nucis vom. ....         | 3ii  | 15 |
| Elix. calisayæ ....            | 3iii | 90 |

M. Sig.: One teaspoonful in water three times a day.

#### Granular Conjunctivitis.

The following has been recommended by *Merck's Archives* as of service in the treatment of granular conjunctivitis:

|                          |        |    |
|--------------------------|--------|----|
| R. Cupri sulphatis ....  | gr. i  | 06 |
| Acidi salicylici ....    | gr. ii | 12 |
| Cocainæ hydrochlor. .... | gr. ii | 12 |
| Petrolati albi ....      | 3iiss  | 10 |

M. Ft. unguentum. Sig.: Apply at night and wash the eyes well in the morning with a boric solution.

#### Fat Diet in Gastric Hyperacidity.

According to the *Ther. Month.* Woldbackmann has recently given attention to the administration of fat, especially in the form of butter and cream, in the treatment of gastric hyperacidity. The good results from his experiments have been substantiated by Rumeberg, Strauss, Penzold and others. The consensus of opinion is that the fat administered in the form of butter, etc., not only causes a diminution of free hydrochloric acid, but also influences the hypersecretion. Under such a diet gastric digestion was never prolonged.

**Chronic Bronchitis in Children.**

According to the *Med. News* beneficial results are obtained from the use of ichthyol in chronic bronchitis, especially as it retards the disintegration of albumins and favors the absorption of exudates when taken internally. It has been employed by W. B. Jennings in several cases with remarkable success. The following combination is recommended by him:

|                     |          |    |
|---------------------|----------|----|
| R. Ichthyol         |          |    |
| Glycerini           |          |    |
| Syrupi aurantii, āā | .....3ss | 2  |
| Aquæ q. s. ad       | .....3ii | 60 |

M. Sig.: One teaspoonful three times a day after each meal. The first few doses sometimes nauseate, but later the child acquires a taste for it.

**Pruritus Ani.**

The following, according to the *Cin. Lancet-Clinic*, makes a very good ointment in the treatment of pruritus ani:

|                         |              |      |
|-------------------------|--------------|------|
| R. Acidi carbol.        | .....gr. xxx | 2    |
| Hydrarg. chloridi mitis | .....5i      | 4    |
| Picis liquidæ           | .....3iss    | 6    |
| Menthol                 | .....gr. xx  | 1 30 |
| Zinci oxidi             | .....5ii     | 8    |
| Cerati simplicis        | .....3ii     | 60   |

M. Ft. unguentum. Sig.: Wash the parts with hot water. Spread the ointment on a cloth, apply to the affected parts and fasten it on with a T bandage.

**Asthma.**

W. A. Wells, in *New York Med. Jour.*, states that the following combination meets with favor among the asthmatic patients:

|                           |             |    |
|---------------------------|-------------|----|
| R. Pulv. stramonii        |             |    |
| Pulv. belladonnæ fol., āā | .....5vi    | 24 |
| Pulv. potassii nitrat.    | .....3iss   | 6  |
| Pulv. opii                | .....gr. xv | 1  |

M. Sig.: To be used in the form of a fumigation. Internally the iodids are of great service in chronic asthma given as follows, according to Fothergill's formula:

|                  |           |    |
|------------------|-----------|----|
| R. Ammon. iodidi | .....3iss | 6  |
| Ammon. bromidi   | .....5ii  | 8  |
| Syr. tolutani    | .....3ii  | 60 |
| Tinct. lobeliæ   | .....3iii | 90 |

M. Sig.: One teaspoonful in water three or four times a day.

**Diet in Pregnancy.**

A limitation of the diet is the best remedy in the treatment of heartburn in pregnancy, according to E. P. Davis in the *Month Cyc. of Pract. Med.* He states that milk should be taken in considerable quantities, and if it causes any gastric discomfort, it may be mixed with Vichy or other carbonated water. As a rule, meat should not be taken more than once a day. Coffee and tea check excretion, and their use in any quantities during pregnancy should be discouraged. On the other hand, there is danger in limiting the diet too much for the woman's strength must be thoroughly preserved. Plenty of ripe fresh fruit should be taken, and if this can not be obtained stewed fruit, or preserves not too sweet or canned fruit. At least one quart of water should be taken daily internally, and externally a cool sponge bath in the morning and a warm bath at night. For nervous restlessness and insomnia there is nothing more soothing. A pregnant woman should be in the open air a great deal and the house should be well aired.

**Sparteïn.**

According to the *Med. News* it is not sufficiently recognized that there are a number of drugs which compare favorably, even if they do not equal the action of digitalis in the treatment of heart disease. Of these drugs sparteïn has been especially studied by Thomas, a French therapist, and he has experimented very largely with the drug in chronic affections of the heart. He finds that it is a reliable diuretic, although it does not stimulate to the secretion of more than three liters of urine daily. It is thus, according to his statement, inferior to theobromin, although frequently more potent than digitalis. In its action on the heart it closely resembles digitalis, although it is a much weaker drug. It acts slowly, but its cumulative

and toxic effects are slight. The principal indications for its use, according to this writer, are chronic myocarditis, commencing asystole, subjective cardiac disturbances and arrhythmia. For advanced cases and for cases complicated by extensive hepatic and pulmonary changes, the more powerful drug, digitalis, is preferable. The dose should not exceed one-third of a grain in twenty-four hours by the mouth or one-tenth of a grain hypodermically, twice repeated.

According to Sollmann, in his text-book on pharmacology, sparteïn acts on the muscle of the heart, making it slower and weaker, and he states that because of the latter action it can not be classified with digitalis, as is sometimes done; for digitalis, although it slows the heart, strengthens the contractions. He further states that the blood pressure is usually lowered when the drug is taken by the mouth, since the depression of the heart is more than the constriction of the vessels which it also produces. The diuretic action is not due to sparteïn but to scoparin, a neutral principle existing with it in scoparius.

**Toxic Amblyopia.**

Dr. Terrien, as stated in *New York Med. Jour.*, has followed for long periods the cases of patients who, after having had large scotoma for white and colors have regained good central visual acuteness. It is, of course, essential that tobacco and alcohol be foregone. For the phenomena of general intoxication when the patient has insomnia and agitation he prescribes at first small doses of opium or potassium bromid. A little later he employs strychnin, either hypodermically or in pills. The former method he considers preferable, the dose ranging from grain 1/60 (.001) to grain 1/30 (.002). The following is his formula when given in the pill form:

|                     |               |     |
|---------------------|---------------|-----|
| R. Strych. sulph.   | .....gr. 1/60 | 001 |
| Quassin (amorphous) | .....gr. 1/6  | 01  |
| Pulv. rhei q. s.    |               |     |

M. Ft. pilula No. i. Sig.: Take one such pill two or three times daily before meals. In addition, where practicable, he employs weak continued electrical currents, one electrode being placed on the back of the neck, the other moved alternately under the eyes. The current should be very mild and should not be strong enough to cause pain.

**Medicolegal.****Prescription of Liquor by Physician also Pharmacist.—**

The Court of Appeals of St. Louis, Mo., says, in the case of *State vs. Hensley*, that it does not understand the law to be that a physician who is running a drug store as a pharmacist has a right, of his own accord, to prescribe for any person, hale or sick, who happens to come round, and then proceed to sell whisky on the strength of his professional officiousness. If a prescription for an intoxicant, issued by a physician, to be filled by himself as pharmacist, is to be anything more than a pretext for illicit sales, it certainly ought to be the honest expression of his judgment as a physician concerning the remedy his patient needs. There is a palpable difference between a case where a pharmacist is a different person from the physician, and has to rely on the latter's direction, and a case where the pharmacist and the physician are the same person. It appears to the court that a man who issues a bogus prescription for whisky as a physician, and then fills it as a pharmacist, is guilty of two crimes, instead of one, and ought to be amenable for both of them. When a sale of liquor is made without a prescription, it is immaterial that one is written after the sale is made, even if it is issued in good faith. The law refuses to accept a "nunc pro tunc" prescription, that is, one made after the time when it should have been made.

**Death from Anesthetics Under Insurance Policy.**—"Anesthetics administered by a regular physician" having been excepted from such injuries as were not covered by an accident insurance policy, the Court of Civil Appeals of Texas says, in *Maryland Casualty Company vs. Glass*, that it might be regarded as an insurance against death from chloroform, independent of all other causes. The burden of establishing the fact that the death of the insured resulted, independent of all

other causes, from chloroform administered to him, was on the party suing for the insurance. In other words, she must prove that the anesthetic was proximately the sole cause of the insured's death. If his death was caused by it alone, the company, by the policy, was liable in the principal sum therein specified. But if he was afflicted with disease which caused or directly contributed to his death, the company would not be liable, though chloroform might have been a cause concurring with his affliction in producing death. If he was suffering from appendicitis, as was shown by the indisputable evidence, and if the anesthetic would not have caused his death had it not been for such affliction, but he died because the chloroform aggravated the effects of the disease, or appendicitis aggravated the effect of the drug, the company would not be liable under its contract. For in either event appendicitis and chloroform would be concurring and inseparable agents proximately contributing to his death, and it could not have been the result of an injury from anesthetic, independent of all other causes.

**Liability to Users for Mistakes in Sale of Drugs.**—The Supreme Court of Appeals of West Virginia asks, in the case of *Peters vs. Johnson*, can a druggist, from incompetency or negligence, sell to one person the wrong poisonous article as medicine, which, being taken by a third person lying sick in the purchaser's house, inflicts injury upon such third person, without any liability upon that druggist to answer to that third person? It says we know that drugs and medicines are kept in homes, and may, and probably will, be used by other persons than the one buying. Such is the probable, usual case. Is it possible that there is no reparation to this third person for irreparable harm to him from such incompetence or negligence? Considering the frightful dangers lurking in drugs, poisons and medicines, this would be a disastrous rule. Is there no duty upon a seller of medicine, as to persons who may use them, beyond the immediate purchaser, simply because there is no contract between the seller and the third person? Where the action is only for the breach of a contract, only the parties to it, or those who stand in their shoes, can maintain it. Strangers can not sue for its negligent breach. But where, in a given transaction, the law puts upon a person the duty to so act that he does not harm others, independent of a contract, he is liable to third parties, even though executing a contract made with a particular person, if he harms others by negligence. If harm may come reasonably and probably to any one from another's action, there is duty on him so to act as to avoid such injury. Now, where a druggist sells medicine to one, is it not probable that it may be taken by others than his immediate purchaser; and if the wrong article and dangerous, is it not probable that others will receive injury? The conclusion reached is that apothecaries, druggists and all persons engaged in manufacturing, compounding or selling drugs, poisons or medicines, are required to be extraordinarily skilful and to use the highest degree of care known to practical men to prevent injury from the use of such articles and compounds. Where a druggist, or, as in this case, a merchant, sells a poisonous drug to one person, for a medicine which is harmless, by mistake, and it is taken for medicine, without negligence, by a third person, the seller is liable to such third person for damage resulting to him therefrom, notwithstanding there is no privity of contract between the seller and such third person.

**Opinion as to Practice of Medicine—Sale of Device.**—The Supreme Court of Illinois holds, in the case of *People, to Use of State Board of Health, vs. Lehr*, that a question was manifestly improper in which a physician was asked to state whether or not, in his opinion, a person prescribing a medical device, claiming that it would cure rheumatism, etc., would be regarded as practicing medicine, as the witness understood the term. The court says that the statute defines the practicing of medicine, and that it was for the jury, and not for a witness, even though he might be called an "expert," to say whether certain conduct amounted to the practice of medicine. In other words, this question sought to have the witness decide the very ultimate question which the jury had been sworn to try, and, consequently, an objection to it was properly sustained. Then it was asked that the jury be instructed that if

it found from the evidence that the party charged with illegally practicing medicine prescribed a certain instrument or device to persons suffering from physical ailments, and recommended it as a means of cure or relief for such ailments, and that he did so without first obtaining a license therefor from the State Board of Health, then the jury should find him guilty and assess his fine as provided by statute. But this instruction, in view of the facts of the case, the court holds, did not correctly state the law. It says that the party did not "treat, or profess to treat, operate on or prescribe for any physical ailment, or any physical injury to or deformity of another." He simply offered and recommended the instrument or device in question for sale. He was practicing medicine, within the meaning of the statute, no more than is the druggist or pharmacist who sells and recommends surgical instruments, atomizers, and innumerable other appliances used by the afflicted. If this instruction should be held to announce the correct rule of law, then any neighbor or friend who might prescribe or recommend the use of a particular instrument or device would be guilty of a violation of the statute, which is certainly not in accord with the spirit of the statute or the intention of the legislature. The evidence not showing that he was an itinerant vendor of the device, he could not properly be convicted of violating section 8 of the statute, which provides "that any itinerant vendor of any drug, nostrum, ointment or appliance of any kind intended for the treatment of diseases or injury, who shall, by writing or printing, or any method, profess to cure or treat disease or deformity by any drug, nostrum or application, shall pay a license," etc., admitting that the device in question was an appliance, within the meaning of this statute. This, like all other penal statutes, must be strictly construed. The statute is a wise and humane one, and, within its reasonable construction, to be rigidly enforced; but any attempt to make it cover cases like this would be an abuse, rather than an enforcement of it.

## Current Medical Literature.

### AMERICAN.

Titles marked with an asterisk (\*) are abstracted below.

#### Medical Record (N. Y.), May 24.

- 1 \*Radiotherapy for Cancer and Other Diseases. William J. Morton.
- 2 \*Benign Tumors Complicating Pregnancy. Bache M. E. Emmet.
- 3 \*Malignancy Complicating the Pregnant State. S. Marx.
- 4 Uterine Displacements Complicating Pregnancy. Edward A. Ayers.
- 5 A New Substitute for Silver Nitrate. Albert C. Barnes and Hermann Hille.
- 6 Bilious Remittent Fever. R. H. Phillimore.

#### Boston Medical and Surgical Journal, May 22.

- 7 \*Gunshot Wounds of the Knee-Joint by the Projectile of Reduced Caliber. Louis A. LaGarde.
- 8 Notes in Cuba. Charles C. Foster.
- 9 \*Birth and Death-Rate as Influenced by Obstetric and Gynecologic Progress. (Concluded.) George J. Engelmann.
- 10 Two Cases of Tetanus Following Vaccination. Lyman Allen.

#### Medical News (N. Y.), May 24.

- 11 \*Consumption Contracted in Colorado and Methods to Restrict Its Spread. S. G. Bouncey.
- 12 \*The Treatment of Puerperal Eclampsia. William E. Parke.
- 13 \*Venesection and Transfusion in Puerperal Eclampsia. R. Abrahams.
- 14 \*Puerperal Hemorrhage. George Seymour.
- 15 \*How Shall We Treat Sepsis Following Abortion or Labor? W. O. Henry.
- 16 \*The Etiology of Puerperal Toxemia. A. Ernest Gallant.

#### American Medicine (Philadelphia), May 24.

## 1. Radiotherapy for Cancer.—Morton concludes as follows:

1. Radiotherapy broadens our conceptions of the possibilities of the therapeutics of modern medical science. 2. The  $x$ -ray has a general application for the relief of pain. 3. As to technic, a standardization as to apparatus and its capacity, and as to duration and frequency of treatments and distance of the tube is recommended to operators. 4. The  $x$ -ray has a curative effect in internal cancer and other internal diseases. 5. For superficial diseases a medium soft tube may be used; for internal cases a hard tube. The hard tube is applicable, however, in all cases. 6.  $X$ -radiation is recommended prior to any operation, to clear the tissue of cancer particles and foci, and to circumscribe the disease. 7.  $X$ -radiation is recommended after operation to preclude a recurrence. 8.  $X$ -radiation may be recommended in place of an operation, and may be preferable to one for the reason that operation secures but a comparatively moderate percentage of permanent recoveries, and because up to date the  $x$ -ray procedure shows a continued improvement in cases, and a percentage of cures which will, undoubtedly, compare favorably with surgical operation. 9. There is danger to the patient or uncertainty as to what might be accomplished when the  $x$ -ray is employed by immature operators. 10. In  $x$ -radiation we possess more nearly a solution of the problem of curing cancer than by any other method of treatment.

2. Benign Tumors in Pregnancy.—The various forms of non-malignant growths that may complicate pregnancy are noticed by Emmet. He enumerates the different forms, including deformities of the spleen, kidney and other viscera, bladder distension, calculus, ovarian tumors, fecal accumulations, exostoses about the pelvis, pus tubes, dermoids, etc. He favors operative treatment in case the tumor is accessible, in the non-pregnant woman, but if the woman has recently become pregnant, he would remove a fibroid of the uterus, if it were large, wherever situated. If it were slow growing and small he would leave it if in the body, but remove it if situated in the lower segment or neck. If the tumor only is discovered when half-way in pregnancy, he would leave it absolutely alone if in the body, but if in the lower segment or neck he would temporize, seeking to crowd it out of the pelvis, and try to tide over until the uterus had become thoroughly accustomed to pregnancy. In the late months he would deal only with those that grow in the neck and of sufficient size to impede delivery. Then he would operate from below. Even then he might possibly decide to await events or induce premature delivery. The tumors may be so general and threatening as to require the removal of the whole uterus even early in pregnancy and such contingencies have to be considered.

3. Malignant Growths and Pregnancy.—Marx thinks that in these instances the individual indications should be followed with the hope of saving the life of the child. He holds that deciduoma malignum occurs early in pregnancy.

7. Gunshot Wounds of the Knee.—La Garde reviews the more recent experiences in gunshot wounds of the knee as follows: (1) We find that the mortality of gunshot injury of the knee-joint in the Civil war was 53.7 per cent., and, as amputation was universally done, all those who recovered escaped with the loss of a limb, unfit for duty; (2) that 33 cases of gunshot wounds of the knee produced by the larger caliber lead bullet in campaign, reported by Reyher and von Bergmann, treated antiseptically, gave a mortality of 11.1 per cent.; (3) that 62 cases produced by a variety of missiles reported by the surgeon general since 1898, similarly treated, gave a mortality of 8 per cent., and that 45.6 per cent. of those who recovered were restored to duty; (4) that of 19 cases in the Santiago campaign by the reduced-caliber bullet the mortality was nil, and that 73.6 per cent. of the wounded recovered fit for duty. It is thus seen that the humane features of the reduced-caliber bullet have operated not only in

diminishing the mortality in gunshot injuries of the knee from about 8 or 11 per cent. to *nil*, but that it has increased restorations to duty 28 per cent., as shown by comparing the last two tables. The foregoing figures relating to the humane features of the reduced-caliber bullet established fully the predictions of von Coler, who said at the conclusion of his experiments with the German Mauser that if it be found that wounds by the small bore are aseptic, joint wounds will be the most favorable of all bone injuries to treat.

**9. Birth and Death Rate is Influenced by Obstetric and Gynecic Progress.**—Englemann says that the review of the figures clearly shows that obstetric and gynecic progress has left no very distinct impression on the vital statistics comparative to the decreasing death rate and the control of epidemics of the present day. The birth-rate is not increasing, it is decreasing. While still-births are decreasing in Europe it is not so in this country. The death rate in child-birth has been reduced somewhat by antiseptic practice, but less in this country than in Europe, notwithstanding the supremacy of midwives abroad. It is still far greater than it ought to be and while the results of modern hospital practice are shown, the splendid record of earlier years of the antiseptic era is not everywhere maintained, and in some of the leading maternities of the country the death rate is again increasing. There is a diminution in deaths from puerperal fever, but those from eclampsia seem to be more frequent. Taken altogether there seems to be some obstetric progress, but the figures are influenced by factors obscuring the influence of medical science. In the high death rate of the child in illegitimate labor, is given evidence of premature interference. In the decreasing fecundity we see the deteriorating influence of refinement, luxury, social aspirations, etc., and whatever the motive, the cause, he says, of diminishing fecundity is the intentional limitations of the family, and medical science yields to human vanity and its desires.

**11. Consumption Contracted in Colorado.**—Bonney discusses the statistics as to the indigenous occurrence of tuberculosis in the state and especially in relation to the report of the tuberculosis committee appointed a year or more back by the state society. He considers that the increase of tuberculosis mortality is incident to the increase in population, the unhealthy occupation of a portion of the population in mining, etc., to direct tuberculosis predisposition on the part of those whose parents came to the state suffering from tuberculous infection, and he questions somewhat whether the reference of the disease as being contracted within the state is always correct. He favors compulsory notification and restriction sufficient to the supervision, and the education of the consumptive and the public, establishing detention institutions for the ignorant and vicious who refuse to submit to the necessary sanitary rules, state sanatoria and segregation hospitals for the poor, the regular disinfection of tuberculous infected apartments, prohibition of expectoration, the formation of societies for the study and dissemination of information for the tuberculous and government supervision of public buildings, tenement houses, factories, etc. While not underestimating the possible dangers, he would have the education of the public rather encouraging than otherwise as regards the disease.

**12. Puerperal Eclampsia.**—After first reporting a case, Parke discusses the theories of the prevention and treatment of this disease. For the former he would look for an easily digestible diet, with a minimum amount of nitrogenous matter, careful attention to elimination in all ways and suitable exercise. If all these fail he would anticipate labor. He thinks well of venesection as being of the greatest value in florid, full-blooded persons. Chloral or bromids are useful in the attacks and veratrum viride in the sthenic cases with the use of normal salt solution under the skin or in the bowel. He believes that accouchement forcé would save more children than allowing the labor to proceed during the convulsive seizures in the natural way.

**13. Puerperal Eclampsia.**—Abrahams recommends venesection and transfusion as important measures in puerperal ec-

lampsia. He says the former causes an immediately favorable change in the woman's appearance; the cyanosis of the face; the rigidity of the muscles; the spasms and twitchings are stopped, and the pulse loses its tenseness, while the coma gradually and surely yields. Transfusion improves the pulse; induces free sweating and micturition; produces intense thirst in the awakened patient which causes her to drink copiously, and this is very desirable. The only precaution in regard to the use of blood-letting would be direct transfusion into the circulatory apparatus instead of waiting for its slower absorption by the bowel. He thinks venesection, as a rule, is indicated in nearly all classes of cases.

**14. Puerperal Hemorrhage.**—Seymour advocates Cesarean section in puerperal eclampsia when the mother is in good condition, uninfected, and not exhausted by long labor. The other forms of puerperal hemorrhage are noticed, with the proper measures to be employed.

**15. Puerperal Sepsis.**—The summary of the treatment of this condition is given by Henry as follows: 1. Remove early, with the finger, sharp curette and flushing, all débris, decidua, blood-clots and sloughing tissue which may be infected, from the uterus and from all raw surfaces of cervix, vagina and vulva. 2. Dry all of these raw surfaces and freely apply to them the 95 per cent. carbolic acid, washing away the surplus with sterile water. 3. Unless hemorrhage require, leave no tubes or packing of any kind in either vagina or uterus. 4. Have a simple carbolized, 2 per cent., vaginal douche used twice a day. 5. Open the bowels freely with calomel,  $\frac{1}{2}$  grain, every hour for four hours, to be followed by Rochelle salts until sufficient action has occurred. 6. Give quinin, 3 grains, every four hours, followed by tincture of the chlorid of iron, 15 drops, in water. 7. Give good nourishment, with milk, eggs and stimulants every four hours. 8. Let this be the routine early treatment. 9. When fixation of the uterus occurs and infiltration takes place in Douglas' cul-de-sac or in the broad ligaments, or when the tubes or ovaries fill with pus in acute cases, open promptly and drain through the vagina. 10. If multiple abscesses occur in the uterine walls, if the walls become badly infected, or if necessary in order to secure perfect drainage for a badly-infected pelvic cavity, remove the uterus and all else necessary by the vaginal route.

**16. Puerperal Toxemia.**—According to Gallant, puerperal toxemia is due to the implantation of pyogenic bacteria within the genital tract, before, during or after labor. They find there a proper culture soil of right temperature in which they thrive and multiply, producing substances which, when absorbed in the system, cause toxemia and give rise to the symptom-complex designated sapremia and septicemia. The introduction of these micro-organisms in the larger portion of cases (barring gonococic cases) is an avoidable offense. Unfortunately, it is not rare; therefore, it is the duty of the nurse, student and physician when in charge of an obstetric case to practice thorough and conscientious asepsis.

**17. Valvular Heart Disease.**—One of the greatest therapeutic achievements of late years, according to von Noorden, is that of overthrowing the idea that absolute rest is required in cases of heart disease. The rules of treatment which von Noorden lays down are: 1. To avoid undue exercise in any case of palpitation of the heart or shortness of breath. Patients should not hurry or exert themselves or become mentally excited. Another important matter is the prevention of obesity which increases the heart's labor. In treating this condition we should act with the greatest caution. The arrangement of the dietary differs in every case and should be carefully studied by the physician. In every case where alteration in the weight of the patient is required it should be done slowly. There should be also a selection and proper distribution of the various items. Too copious meals should be always avoided and frequent and light meals are preferable. We can not recommend a permanently vegetarian diet: a reasonably mixed diet is best. Under no circumstances should the stomach be overloaded. The introduction of liquid must be likewise carefully watched. Too much must not be taken at meals. The total quantity allowed

daily is also of importance; a certain amount of restriction is often advantageous, and we should not allow the patient, for instance, as a rule, to drink more than 1¼ liters or 2¼ pints, avoiding strong infusions of tea, coffee and alcoholic beverages unless there is some therapeutic reason for their use. He does not absolutely forbid small quantities of stimulants, even tobacco, in patients with heart disease. Digitalis should be avoided in perfectly compensated cases. Muscular exercise should be advised; the best is slowly walking up hill where that is possible. He thinks rowing properly gauged is of advantage. Bicycling, tennis, golf and such sports invite excess. Room gymnastics have a limited value if not overdone, and massage has its limits of usefulness, but he is very much opposed to allowing a non-medical masseur to vibrate the heart. In patients whose hearts are very excitable and have a most disagreeable sensation at the slightest exertion, which makes the gymnastic treatment almost impossible, vibration is one of the best cardiac sedatives, and he uses a special apparatus for the purpose. Hydratic treatment is also mentioned, and he speaks of the Nauheim baths as being specially valuable in recent cases, but it is bad practice for those with severe loss of compensation to take them. For the last two or three years he has used the electric baths after the system of Dr. Schnee, consisting of four porcelain tubes, in which the four extremities are immersed, the patient sitting in a comfortable chair. The momentary as well as the permanent effects are similar to those of the carbonated baths and the switchboard permits the use of the different forms of the current as desired.

18. **Neuritis.**—Kuh's article is a review of the subject in all its aspects, including the associated psychoses and trophic conditions which are associated with inflammation of the nerves.

19. **The Vermiform Appendix as a Cause of Intestinal Obstruction.**—Summers reports a case in which intestinal obstruction was caused by a constriction ring produced by the appendix adhering to the mesentery and notices other facts observed of this character, and mentioned by surgical authorities.

25. **Ascites in Abdominal Tumors.**—Osler has recently noticed a case and has compared statistics in the Johns Hopkins Hospital where there have been ten patients of this kind out of 9400 cases, all recovered after the operation. The condition is one to which the attention of the profession has not been specially called. The question of operation is an important one. A solid ovarian tumor is usually benign; the cases in Dr. Kelly's clinic all uniformly recovered.

26. **Intestinal Obstruction.**—Packard reports a case and calls attention to the possibility of the hitherto undescribed condition of an intestinal loop acting as a plumber's trap, producing intestinal obstruction. Such loops might follow adhesions from any inflammatory condition and might remain symptomless until the weakening of the intestinal walls from some cause or other led to accumulation of the contents of the loop sufficient to cause obstruction. In such cases it is doubtful whether remedies tending to render fluid the contents of the intestinal canal are of advantage and he is inclined to think that even they may cause a formation of such a loop in the parietic bowel. The latter part of his article deals with the action of eserine as an intestinal stimulant, with the report of cases in which it was effective in meteorism, and reviews the literature of such action of the drug. In these cases he gave 1/50 of a grain of sulphate of eserine every third or fourth hour. Other authorities have had good and permanent results with it. Von Noorden uses the salicylate of eserine on account of its advantage of preservation in the dry state and it is soluble in water. He says it can be best given in powder with milk sugar.

27. **Insufficiencia Pylori.**—This condition is one in which no appreciable quantity of chyme can be aspirated one hour or less after Ewald's test meal, and whatever is aspirated is coarse in appearance. This condition of little or no chyme has usually been interpreted as indicating compensatory hypertrophy of the muscular coat. It usually is due, according to Knapp, to chronic catarrh and the normal closure of the pylorus is due to irritation of the mucous membrane. In the condition

here discussed the stomach has become insensitive and there is no irritation to close the orifice. It ends in atrophy of the mucosa and may give no symptoms of the disease. The main phenomena relating entirely to interference with normal function of the intestines are such as headache, vertigo, nausea, intestinal discomfort, constipation, diarrhea, eructation, etc. The treatment depends on the stage of the disease; we should see if there is no gastric digestion present and how readily the stomach empties itself. The drugs used must be calomel, to aid the intestinal digestion, the combination of sodium and magnesium, rhubarb, ammonium chloride, pancreatin and bile in the form of inspissated oxgall. These are about all the drugs necessary. If the stomach is empty immediately after eating, the drugs can be taken at once, but if there is still some digestion in the stomach they should be timed accordingly. He gives the diet for these cases, forbids the use of coffee and tea, rich cocoa, carbonic acid waters, alcohols, white meats, beans and peas unless their cellulose covers are removed, turnips, spices, tomatoes in every form, everything prepared with vinegar, grapes, peaches, plums, prunes. Of fruits very little should be taken, and they must be peeled. Milk must not be permitted *ad lib*. He believes in thorough mastication and if the teeth are bad the food should be ground up. Half teaspoonful doses of sulphate of sodium in a glassful of hot water, taken hot, about half an hour before each meal, will clean the stomach. In diarrhea there is but one drug he has learned to rely upon, strychnia, beginning with 1/30 of a grain and running up to even 1/7 three times a day. It causes diminution in the number of stools and increases the consistency. His usual prescription is one-half a teaspoonful of sodium sulphate in a glass of hot water half an hour before meals and the following after meals:

|                       |    |
|-----------------------|----|
| R. Natr. bicarbonate  |    |
| Magnes. ust., aa..... | 30 |
| Pancreatin .....      | 5  |

M. Ft. pulv. D. Sig.: Teaspoonful after meals as directed.

How long after meals it should be given must be guided by the result of the examination. He reports twelve cases, all females but one, but he does not venture to say anything in regard to the relative frequency in the two sexes.

28. **"Fourth Disease."**—Pleasant has had a number of cases under his care presenting symptoms suggesting "fourth disease" and analyzes the symptoms. He thinks that Dukes has not established the existence of any new exanthematous disease and that under his so-called "fourth disease" he has included cases of undoubted scarlet fever and probably cases also of rubella. In certain epidemics scarlet fever may present an atypical picture, with many of the classical symptoms absent, rendering a diagnosis difficult or impossible in isolated cases, and a satisfactory classification of exanthematous diseases is hardly to be hoped for until we know more of their etiology. In the meantime we should be slow in accepting new diseases.

29.—See abstract in THE JOURNAL, xxxvii, p. 851.

31. **The Roentgen Rays.**—The tissue changes caused by the Roentgen rays with the various grades of x-ray burns, are mentioned by Beck, who points out that the characteristic difference between them and ordinary burns is the incubation period in x-ray burns. The special point of his paper is the action of these rays in integumental and other malignant disease, which he claims is in the nature of a chronic inflammation. The nutrition of the superficial strata is disturbed, a cell starvation is produced, and if overirradiation is continued, necrosis may result. In this way we understand the curative effect in lupus, carcinoma and sarcoma, especially if they are confined to the integument. We should consider the use of this agency not only in the cure of disease, but in the after-treatment of surgically treated cases. The carcinoma cells, which are often left in the tissues and which can not be reached by the knife, may be the cause of further malignant growths. He remarks that even when cure can not be obtained the influence of the rays may be beneficial in influencing pain, etc., illustrating this fact by the report of cases where the adenocarcinomatous growth had reappeared following removal, causing great

pain and extending deeply into the tissues. In such cases the hard tubes must be chosen, while in skin neoplasms soft tubes are preferable. His observations suggest to him the use of the x-ray as soon as possible after the removal of the neoplasms and kept up for a period of several weeks. It is advisable to expose for only five minutes at first and after a week for about ten. If after the third exposure two weeks after the first, no reaction follows, the application may be made two or three times daily and at last daily unless reaction shows. During the tentative exposures, the distance of the tube should be four inches, later on it may be one inch only. He has seen no harm from direct contact. He does not favor the use of a shield in neoplasms as the influence of the ray should be extended as far as possible. During the interval between the application xeroform salve (1 to 10 of lanolin) should be employed.

**32. Albuminuria.**—The new method described by Boston consists in using a pipette which he dips into the urine a short distance and closing the top with the finger extracts a small portion. He then washes the outside of the pipette off carefully with water and dries it and then inserts it in a bottle of nitric acid. Slight removal of the finger tends to allow the acid to float the urine up in the pipette, the usual reaction occurring at once at the junction of the two liquids. He believes that this method is better than the usual methods of employing Heller's test. The different reactions of serum albumin, mucin, globulin, urates, uric acid, indican, etc., are described as also other tests and reagents that are used.

**33.**—See abstract in *THE JOURNAL*, xxxvii, p. 1481.

**34. Tracheal Injection.**—Rockwell favors the use of the tracheal method of introducing medicines in bronchial and lung diseases, reporting cases where it appeared to be the most effective method. He asks why we should make the stomach the sole distributing point for remedies intended for all parts of the body when we have the right of way by a shorter route.

**39. Inflammatory Diseases of the Adnexa.**—Ehrenfest pleads for conservative treatment in these conditions and concludes that the conservative non-surgical treatment will give good results in almost all cases of acute or chronic non-suppurative inflammations of the uterine adnexa. In suppurative cases the non-operative treatment should be tried, unless symptoms make operation imperative. It gives usually comparatively good results among the well-to-do, but unsatisfactory ones among the patients of the working classes. If operation is decided on the radical operation will be the operation of choice and vaginal drainage the method of necessity. For radical operation the vaginal route should be always given preference.

**46. Protection of the Cornea.**—Gifford employs a method of covering the cornea in sightless stumps in certain cases where the corneal tissue remains and is likely to cause irritation, by the use of conjunctival flaps, the Thiersch flap, or an epithelial lip flap. In most cases where the conjunctiva is used the membrane is excised around the lower half of the cornea for an area about 3/16 of an inch wide at the sides, and 1/8 inch below. Above this zone the membrane is dissected free from the globe as far as the upper fornix, in the neighborhood of which a cross cut is made through the membrane to allow it to be slid down over the cornea without putting too much tension on it. Three sutures below are generally sufficient, but these should be put well into the episcleral tissue nearly as deeply as in the advancement of one of the straight muscles. Dissecting up the conjunctiva both above and below and sewing it together in a straight line across the center of the cornea has not been successful in his hands. If the conjunctiva is atrophic and the space for an artificial eye be too much limited by the operation just described, he uses the epithelial lip flap, a thin flap shaved from the lip with a razor, or the Thiersch flap, dissecting up the epithelium for 1/8 of an inch around the cornea and scraping the latter (taking special care in the neighborhood of the limbus), the flap is spread out carefully over the cornea and tucked under loose conjunctiva on all sides. It is well to bandage both eyes for twenty-four hours after these operations. He has used the Thiersch flap once, but the accumulation of deep epidermis on its surface caused some irrita-

tion and he then scraped the skin flap off and substituted a lip flap for it. He thinks, however, with certain precautions this method might succeed.

**50. Atroscin and I-Scopolamin.**—Macklin has investigated these drugs and gives in tabulated form the results with a 1 per cent. solution in castor oil. He finds these rapid and powerful mydriatics, and as cycloplegics they are as potent and reliable as atropin sulphate, while the power of accommodation returns in five days. The advantages of the oily solution are: 1. Only one application is required. 2. More rapid and certain action of the drug. The table shows that mydriasis begins in ten minutes and is complete in twenty. 2. Cycloplegia begins in ten minutes and is complete in about fifty (average). 3. The power of accommodation returns to normal in five days (with occasional slight variations). The drugs never fail to give him satisfactory results and he thinks that ought to always be used in preference to homatropin in school children and all other persons with active accommodation who can possibly afford the necessary five days' time.

**76. Human and Bovine Tuberculosis.**—Ravenel's article is a very important one containing numerous experimental observations and reporting several cases. He thinks that we can, in the absence of evidence otherwise, assume that bovine tuberculosis is virulent to the human species and rather believes that we ought not to entirely exclude bovine infection even in those cases where the abdominal organs yield a culture of feeble virulence, as we know nothing about the effect produced on the bovine bacillus by prolonged residence in the human body. It is at least possible, he holds, for it to become radically changed in the human body so that it will show the cultural and pathologic peculiarities of the human type. His conclusion is that the human and bovine tuberculosis are slightly different manifestations of the same disease, and that they are intercommunicable. Bovine tuberculosis is therefore a menace to public health, to what extent is impossible to determine, but its existence cannot be denied. In the past the tendency has been to exaggerate, but this does not justify us in belittling the risk, and it is folly to blind ourselves to it.

**86. Cystoscopy.**—Schmidt first notes the popularity of the cystoscope at the present time, and then points out what he thinks are some of the fallacies or errors that are likely to be met in its use. We should never be satisfied with the results of trigonum examination unless all the views taken from the different positions of the cystoscopic beak are uniform in their general features. It is not uncommon that a portion of the free plane of the prism is covered by a fold of the urethral mucosa, and the whole field of view is covered with a reddish tinge, giving the idea of inflammation which does not exist. Another thing that leads to error is the fact that the ureteral openings lie in different cases at entirely different distances from the urethral orifice, and they are often overlooked because they are almost hidden in the folds, and the cystoscope is pushed far into the viscus in the search for the ureteral openings, while the prism has already passed them. In cases of inflammation or edema it may be very difficult to find the openings and damage may be done to the patient by poking around and because the cystoscope fails to detect the opening. If there is any doubt as to whether one of the probable ureteral openings or niches is in fact the ureteral entrance, the finger may be introduced either into the vagina in the female or the rectum in the male, and this finger presses the doubtful area toward the cystoscopic window, exposing the bottom of the niche to make possible the decision whether in its depth the ureteral opening is to be found or not. In case the niche can not be observed there is nothing to do but to watch carefully the symmetric area or the place where it ought to be in relation to the other ureter and watch for the flow of urine. This can be facilitated by giving the patient methylene blue some time before the examination. There are also other sources of error in the examination of the internal urethral orifice. The parts are seen when they are very close to the cystoscopic window and are magnified and there are, moreover, changes in the formation and appearances by the introduction of rigid straight instruments of considerable size. Often either

hypertrophied or edematous folds of the internal urethral orifice have imposed upon the observer as tumors or polypi. They are, however, usually multiple and not transparent like polypus. The use of the cystoscope as a preliminary to the Bottini operation is an important matter and he calls attention to the dangers. We should notice the following points to make sure that the barrier belongs to the bladder and can be safely operated on. The protrusion and elevation into the viscus must appear as covered with bladder mucosa and not with the urethral mucosa. The bas fond behind the barrier must be a deep one. If the ureteral orifices can not be seen, there is always cause for suspicion that the tumor was pushed into the bladder. Frequently a mistake is made in the diagnosis of a trabeculated bladder, caused by contraction due to the touch of the beak or heat of the lamp and the trabeculated bladder should be diagnosed only when the trabeculation is a uniform one, all over the fundus and vertex, and when examination of the different parts proves that the protrusion of muscular bundles is a constant one. Edema bullosum is a condition which leads to erroneous diagnosis and tumors which are covered with incrustations are sometimes taken for calculi; pedunculated tumors, which cover their pedicle, may be considered malignant on account of their broad base. Varicose nodules occasionally present themselves as tumors. He specially calls attention to the diagnosis of cystoscopic burns as idiopathic ulcers. They, however, heal up in ten or fourteen days, which is never the case with actual ulcers.

**88. Transverse Arrest of the Head.**—Reed summarizes as follows: Deep transverse arrest of the head is a relatively common complication in labor. The diagnosis is easily made from the position of the sagittal suture and the fontanelles. The normal termination of the case can not be awaited in most instances, but forceps should be applied as soon as it is evident that rotation will not occur spontaneously. The blades should be applied in that pelvic oblique diameter toward which the occiput lies. Location of the occiput must be determined before the blades are applied. Traction and rotation must be simultaneous.

**98. Acetozone.**—This substance, benzoyl-acetyl-peroxid, which is also called benzozone, is found a most efficient antiseptic by Wasdin, who says we may conclude: 1. That the peroxid is sufficiently germicidal under conditions favoring its hydrolyzation. 2. That it is innocuous to man and animals, being readily secreted through the kidneys as hippuric acid. 3. That in the treatment of typhoid fever and other bacillary diseases it is directly applicable to destroy the primary colony, provided it can be brought into contact with it. 4. That its special application in typhoid fever enables us to obviate intestinal infection and absorptive toxemia therefrom, thus favoring the formation of protective anti-bodies and limiting, in many cases, the disease to its normal cycle. 5. That in those cases of inefficient reaction in typhoid fever its use tends to make the patient much less uncomfortable, thereby offering better results from appropriate serum therapy.

**99. Purulent Ophthalmia.**—Hansell employs a solution of permanganate of potassium in the treatment of purulent ophthalmia and notices the details. He does not make this solution stronger than 1:600, but employs it in this strength in those severe cases in which the discharge is thick, yellowish and abundant, and the gonococci are abundant, irrigating the eye by means of a nozzle attached to a rubber douche bag, guiding the solution into all portions of the conjunctival sac, and allowing it to discharge over the face on a rubber sheet and then into a receptacle. He repeats this every twenty minutes during the first twenty-four hours, when, if the discharge is lessened, the strength is reduced and the intervals increased. It should be done with a gradually weakened solution up to 1:2000 as long as pus is found in the conjunctiva. He thinks other remedies he has employed, boric acid, bichlorid, formalin, etc., are inferior as germicides or as curative agents to the permanganate.

**100. Sciatic Neuritis.**—Mettler maintains that sciatica is always a neuritis, and that there is no such thing as purely functional neuralgia in these cases. Counter-irritation, even

to actual cauterization, the use of vasomotor sedatives internally, cathartics, diuretics and diaphoretics are the chief measures to be depended on in the subacute and acute stages. Analgesics, narcotics and sensory depressants produce less permanent results in sciatica than they do in other forms of neuralgia, doubtless because they do not affect the organic changes underlying the trouble. Absolute and general rest even to the point of strapping the limbs if necessary is the sine qua non of the acute stage. He uses salicylates and colchicum. Nerve-stretching may possibly do some good by breaking up old adhesions and restoring the circulation. In the chronic stage he prefers the subcutaneous use of strychnia in dose of 1/70 to 1/20 of a grain twice daily. Massage, baths and the steady use of mild currents of electricity should be also employed.

**103. Tuberculin.**—Von Ruck defends the use of tuberculin as a diagnostic agent and claims that if properly used it is not dangerous. As a therapeutic measure, he also advocates it and claims that the very best results have been obtained. Those who have failed should consider that the successful employment of tuberculin, both as a diagnostic and therapeutic agent, implies something more than the routine of giving hypodermic injections and if they give the same amount of study to this as they do to other subjects in medicine they would find in it a most favorable adjuvant in the diagnosis and treatment of tuberculosis.

**113. Rectal Valves.**—Martin defends his assertions as to the existence of rectal valves, describes their anatomy and function and their action in producing constipation when they are abnormal. Hypertrophy of the rectal valves should be recognized as the initial step in the formation of stricture. The treatment of valvular obstruction consists in instrumental massage of the obstruction by means of cotton-covered forceps through the proctoscope and spraying the intestinal tract with a solution of nitrate of silver and rectal irrigation by means of saline solutions in a temperature of from 120 to 140. In such cases the anus should be protected by the proctoscope and the patient be cautioned not to lie on his back or to ride in a carriage or on a street car, which would tend to the congestion of the parts.

**125. High Temperature.**—The title of this article explains it, but the details are interesting. The patient appeared to have been somewhat hysterical; the thermometer ranged from 114 to 94 at different periods. The observation was made by a number of physicians in the Maine Eye and Ear Infirmary. The patient was a young woman 21 years of age in whom there was no special disturbance or general symptoms to account for the abnormal temperature. After the operations the temperature remained normal for some time and, therefore, they can hardly be held responsible in their immediate effects. There was certainly some disturbance of the heat-controlling centers, but how is a mystery. The impression of those observing her was that she was hysterical and this only can be given to account for the condition observed.

**145. The Suprarenal Gland.**—A new use of the suprarenal gland here suggested by Meara is the application of a strong preparation to the mucous membrane in pruritus vulvi and ani. He reports cases in which the treatment was a great success.

**165. Dislocation of the Astragalus.**—After reporting a case, as indicated in the title, Jepson says that his own experience and the results of recorded cases lead him to believe that it would be rarely possible with our present knowledge and technic to bring about a reduction of a backward dislocation of the astragalus without opening the joint and bringing about a reposition of the bone by direct manipulation. With our present command of aseptic surgery he sees no reason why this should not be undertaken in all cases uncomplicated by severe infection with good prospects of securing a nearly perfect result. Removal of the astragalus may be reserved for such cases where the bone is completely separated from its ligamentous attachments, consequently having no adequate source of blood-supply. Amputation should be resorted to only in such cases where the dislocation is compound and infected to a degree impossible

of removal, and the patient's life jeopardized by the septic intoxication or infection.

174. **Tetanus.**—In the case described by Higginson, anti-toxin and carbolic acid treatment both failed and he started to use creosote in large doses. Twenty minims of beechwood creosote (Merck) was administered in a dram of olive oil, hypodermically, morning and evening, still using chloral and morphin. Benefit was observed in a short time and the treatment was continued for twenty days, diminishing the dose of creosote daily. The patient was then able to stand up, but some rigidity persisted, but after a rather slow convalescence the patient was entirely well and regained his flesh and strength in three months. In no case did the creosote produce any untoward symptoms and at no time during its administration was the urine rendered dark or smoky.

178. **Trachoma.**—The only proper treatment for trachoma in Bulson's opinion is the surgical one and he has found a modification of Knapp's operation, consisting in thoroughly scarifying the larger and thicker masses of trachomatous tissue and then applying the roller forceps, most useful. The scarifying renders it easier to express the follicles without excessive mangling of tissue and possible unnecessary destruction of conjunctiva through the forcible pressure exerted. Following the roller treatment the brushing treatment with 1 to 500 bichlorid solution may be employed, but with less vigor than advocated by Fox and others in the performance of the regular grattage operation. Of course, operative treatment is not applicable to the acute inflammatory type of the disease nor to the exacerbations of the chronic stage which should be treated only with cold applications and antiseptics. In all cases the operation should be supplemented by medicinal applications and rigid attendance to hygiene. The sequelæ of trachoma are also mentioned and he thinks that in entropion the Hotz operation is really the best. Of course, any treatment applies only to cases that have not gone too far and produced structural alteration beyond the possibility of securing absorption in the corneal infiltrates which obscure vision.

1. **Dysmenorrhea.**—There are two causes of pain in menstruation, in one case it is due to the physiologic congestion of the organs preceding the discharge, in the other to the contraction of the uterus. The former is the discomfort commonly felt by the majority of women. There is one special morbid condition which produces abnormal congestion. If the uterus is bent back and the utero-sacral ligaments are well marked and firm, the veins which return the blood from the corpus will be pressed on and the return of blood be hindered, producing pain both at menstruation and at other times as well. In some cases the pain is referred to the ovaries, but ovarian menstruation has been used as a name, not as an explanation of the case. The severity of the pain depends not only on the local cause but upon the imagination and sensitiveness of the patient. A correct account of these feelings is not always given. The contraction pains are little felt in most women, but in a few they are painful. Actual obstruction is caused rarely from obstruction in the canal. Sometimes the endometrium, instead of breaking down, is shed in large pieces; this may cause obstruction. This special menstruation disorder is rather

common, according to Herman. Antelexion he does not believe is often the cause of pain and stricture of the os externum is never seen except in diagrams. There is little evidence in his mind as to the incomplete development of the uterus being the cause of dysmenorrhea. In most of these spasmodic cases the function commences at the usual age and it has been in his experience quite exceptional to find the uterus comparatively smaller than it ought to be in spasmodic dysmenorrhea. In some of the worst cases there is neither narrowing of the canal nor the passage of membrane. The disorder usually begins before twenty-five years of age, but may begin later. With our present means of investigation there must be a certain amount of unavoidable error in the diagnosis of dysmenorrhea attacks. We have no means of definitely determining the character of the pain or even its presence. The pain of spasmodic dysmenorrhea is short and remittent, not relieved by lying down and has no tendency to a spontaneous cure. Its natural cure is by pregnancy. It is often, however, accompanied by sterility, which may be cured by dilatation. In about one-third of his patients who were married and sterile the cure was followed by pregnancy. The best drugs for the relief of uterine colic are antipyrin and phenacetin. They are adequate in slight cases and their occasional use is not harmful. In some very bad cases powerful narcotics have to be used, but this is a bad plan. In a few cases he has found guaiacum removes the pain. He does not know how it acts nor how to pick out the cases that it will cure. The local treatment is to dilate the cervix. It is not invariably effective, even pregnancy does not always produce a cure, and if all treatment fails the removal of the ovaries may be required. This, however, should be avoided as long as possible, especially in young women, to whom the effects should be fully explained, Herman says, through some near female friend or relative in whom she has confidence.

2. **Premature Infants.**—Ballantyne describes the conditions of the unborn child, and especially the child born shortly before term. The premature infant is a fetus without one of its most important organs, the placenta; it also lacks the liquor amnii and membranes, which together go to make up the fetal annexa until the proper time for birth. Physiologically it is partly a fetus and partly a newborn child. We see fetal physiology trying to cope with neonatal conditions; the neonatal physiology hindered in its action by the persistent fetal conditions. First, the matter of temperature. The fetus is not required to manufacture heat in order to maintain its body temperature; the newborn infant is, and usually succeeds, but the premature infant is usually called upon to do so, and has only the tissue metabolism of fetal life slightly reinforced by that of an imperfectly established pulmonary respiration to aid him. His liver, moreover, which has been engaged in supplying the blood, is called upon to form bile, and to continue to form blood. The blood itself contains more nucleated xanthocytes than the full-term fetus and the jaundice of the newborn, which has been ascribed to breaking down of the xanthocytes, is very common in the prematurely born infant and the most active area, the placental, is cut off and the heart is called upon to send a specially large supply to the lungs, which it can not fully succeed in doing. There are also more exacting demands upon the new function of digestion. All the physiologic activity of the placenta, which has been in full play in its supplying chemical nutrition, is destroyed and its action of keeping out the invasion of toxins and bacilli is lost. The premature infant in its pathology is midway between the fetus and the newborn child and the closure of the umbilical arteries and veins is apt to be incomplete, and offers an avenue for infection and the ordinary routes of infection are also especially vulnerable. On the whole, he offers less resistance to the pathogenic organisms than the full-grown fetus. In managing the prematurely born infant we must try to continue the fetal phase of life after birth occurs; hence, try to keep up animal heat by the incubator, aid the lungs as far as possible by some method of exciting respiration—in this, Ballantyne prefers the alternating flexion and extension of the trunk of the child as it lies in the palm of the obstetrician's hand, having been first

carefully wrapped in cotton wool. Its food requires certain modifications. Human milk is lacking in iron, and he thinks it well to add iron to the food of the prematurely born child, and he has employed it in the form of liquor ferri peptonatus, though he can not say as yet as to any pronounced results from his experiments. If human milk is not available the prognosis is much more serious. It is well to keep the child in the dark as light may stimulate the eye muscles to act and lead to strabismus. With every care the child will often fail to survive. The problem of the premature infant, he says, is urgent.

**3. Mammary Cancer.**—The title of Bryant's paper explains the subject and he finds that the interval which may take place between the primary amputation of the breast for cancer and its occurrence in the scar or the second breast when such occurs is most uncertain. While in one-half the cases tabulated recurrence took place in 5 years or less, in the other half the interval was from 6 to 32 years, and at least in two-thirds of the cases occurred after ten years. Even when two or three operations were undertaken, the prospects of life were not bad. In 14 cases there was recurrence about the scar of the original operation, in the scar of the axilla in 1; in the sternum in 3 cases and in the second breast in 10 cases and in 5 of these the scar of the first operation was likewise involved. He suggests that the surgeons who advocate the clearing out from the axilla of all lymphoid tissue in every case should consider this fact. In only one of the cases he describes was the axilla cleaned out; this is not his custom and these results would not suggest a change of the operation. He thinks that the results of operation would be much better than they are now if they could always be undertaken during the early periods of the disease, as shown by the majority of his cases; that every breast tumor, neither clearly inflammatory nor encapsulated, which seems to involve the gland tissue and may therefore be cancerous, should be at once explored and removed, if found to be cancerous, with the whole gland and then cancerous growths when localized should be similarly treated. In advanced and neglected cases, the more thorough operations of Banks, Halsted, Gould and others may be used, and in cases of recurrence not favorable for operation, unless the removal of the ovaries should be found to be successful in the future, the x-ray should be employed.

**4. Mammary Cancer.**—Drew has been in the practice of removing the pectoralis minor in his operation for mammary growths and has found that it produces very little trouble in the after-condition of the patient. He thinks in most cases where this has been left the nerve supply has been cut off and the results are practically the same.

**8. Discharges and Douches.**—The douche or irrigant should have for its object the mechanical removal of morbid secretions, accumulations and foreign bodies or it may be used for antiseptic purposes or for the diagnosis. To be satisfactory in any of these it must conform to certain requirements: 1. It should be solvent of substances to be removed when practicable. 2. The reagent should be itself readily soluble in water and form a clear solution. 3. It should be non-irritating to the mucous membranes and sensitive surfaces. 4. To insure thoroughness it should possess the power of penetrating the surface tissues. 5. It should be miscible—chemically compatible—with the most effective antiseptics. 6. It should be economical in cost and reliably available. The most important of these essentials is the power to dissolve the discharge. It is well to know the character of the discharge, such as catarrhal discharges consisting mainly of the alkaline solution of mucin with globulin and serum albumin. Mucin is readily soluble in a weak solution of alkaline salts, but insoluble in acid, while cells and the serous globulins are soluble in weak solutions of neutral salts. Serous discharges rarely call for special removal except when localized. The pus varies considerably according to its production and its age. Usually it is soluble in a weak solution of neutral or alkaline salts respectively. Cerumen also varies. It is ordinarily soluble in alkaline salts, but it may be so hardened that softening by means of a strong alkaline solution, preferably in glycerin, is often expedient as a preliminary to the douche. Plastic exuda-

tion consists chiefly of filamentous fibrin entangling leucocytes, is very difficult of solution and rarely admits of more than a softening process by the neutral and alkaline salts. The same applies to blood clot. Wingrave gives a tabulated statement of the solvents and precipitants, and points out that many of the salts familiarly used, such as mercurial salts, phenol, boric acid, etc., are not solvents, but actually coagulants in soluble compounds. The best solution apparently seems to be the sulphate of sodium which has the power of mixing well with and diluting most substances and penetrating the tissues. Calcium chlorid, though not so good, is valuable as a hemostatic douche. Borax (sodium baborate) has the advantage of possessing some antiseptic properties. The strength of these solutions should be varied, not over .5 to 1 per cent. The salts of zinc are largely astringent and should be only used as such. Carbolic acid should be mixed with a solution of sodium sulphate or carbonate to make it more efficient. Peroxid of hydrogen has the great disadvantage of causing rapid effervescence when mixed with pus, and this is extremely awkward. The best disinfectants for douches are precipitants of proteids, and these are such as carbolic acid and biniodid of mercury, potassium permanganate, and so on. When mixed with sodium sulphate they are very good. He gives a list of formulæ and instructions for the employment of the douche and protests against the old-fashioned syringe, which is an infection-bearing and dangerous instrument. He illustrates his own instruments. No apparatus is satisfactory in which the same aperture suffices for filling and emptying.

**11. Children of Insane Mothers.**—Tredgold has analyzed 38 cases of children born from mothers while they were insane, 13 of these are living, 25 are dead. Twenty-two out of the 25 died before the completion of the first year. Of the 13 living, 10 are normal, 3 of these cases present evidence of morbid heredity. The conclusion which he thinks can be drawn is that the mental and physical condition of the child is in no wise interfered with by the mother's being insane during pregnancy. Neither is the condition of the child influenced by the variety of the insanity, the duration of the attack or the age of the mother, nor directly by the number of attacks from which the mother may have suffered, but its condition is directly dependent upon the presence or absence of morbid hereditary influences.

**13. The Surgery of Glycosuria.**—This article is concluded in this issue and it appears from Phillips' studies that most of the principal major operations have been performed with a large amount of success. The operations of expediency were singularly successful. The percentage of sugar in the urine is no criterion as fatal results have followed from coma where no sugar had been present for some time. We must take into account with the lowered vitality produced by the circulation of the abnormal amount of sugar, the presence of arteriosclerosis and nerve degeneration, especially as regards the occurrence of sepsis. As regards coma he thinks that general anesthesia is attended with some risk, though not every case of coma is necessarily diabetic. Thorough examination of the urine should be made in all cases, not only as to the amount of sugar, but the presence or absence of acetone or acid bodies, etc.; the amount of ammonia must always be estimated. 1. No operation save of the extremest urgency is to be performed if there is over one gram of ammonia excreted in the twenty-four hours, until this has been reduced to the normal amount. 2. An operation should be postponed if there be aceto-acetic acid in the urine, though the ammonia be not markedly increased. 3. Much albumin in the urine is a bar to operation. 4. If serious disease of other organs, such as the liver, be present an operation should be avoided. 5. Rapid wasting in a stout diabetic not obviously dependent on the surgical lesion demanding treatment should be a reason for postponing an operation until the general condition is improved. An operation should be performed: 1, for malignant disease, if, apart from diabetes, such would be urged; 2, in the case of large abdominal tumors, especially in females. 3. In diabetics of good health without extensive arterial or nerve degeneration cosmetic operations may be performed, especially in females. 4.

An emergency operation is to be undertaken even in the most unfavorable circumstances, but a very guarded prognosis is to be given. Save in the last category, if any of the indications against operation be present the operation should be postponed until they are ameliorated. In all cases in which delay does not mean loss of the patient a careful diet should be adopted and drug treatment is necessary. If ammonia be present in excess sodium bicarbonate should be administered daily until the percentage becomes normal. The actual amount required may be as much as 30 or 40 grains per day. If it should make the patient vomit it should be given per rectum. This treatment lessens the risk of sepsis and coma. Local anesthesia is preferable to general, if possible, and if general anesthesia is employed ether may possibly be safer than chloroform. In any case sodium carbonate is to be administered for a few days before and after, and the increased vulnerability of the tissues should be kept in mind, and strong antiseptics should be avoided. The patient should not be considered cured until the wound is entirely healed. In operations on the urogenitals where internal antiseptics is difficult to maintain an internal antiseptic such as urotropin should be administered.

**15. Pulmonary Tuberculosis.**—Philip lays down the following points as regards certain features of the course of pulmonary tuberculosis; the history of the case, when placed on open-air lines, shows a remarkably rapid return of temperature to the normal. In a certain percentage of cases the fall of temperature to normal does not occur so rapidly, but the ultimate return is frequent enough, if proper treatment be maintained throughout, though it may be delayed for several months. The temperature may remain almost continuously normal even when abundant evidence of moisture is present, and other signs suggestive of the existence of considerable disease in a state far from latent. This he thinks is important, but not sufficiently recognized. A low temperature must not be accepted as an expression of the quiescent or chronic stage. When the temperature is disturbed, either continuously or recurrently, such disturbance should not be attributed vaguely to tuberculosis. A definite superadded cause of disturbance should be sought and may commonly be found. It is the height of folly to attribute pyretic disturbance occurring in the course of pulmonary tuberculosis vaguely to the tuberculous disease. Tuberculosis per se plays a minor part in the production of pyrexia and the search for the cause should be thorough.

**18. Childbirth in Deformed Pelvis.**—Heuze reports 23 cases of flat rachitic pelvis between 8.5 and 9.5 cm. in diameter. Only 3 of the 8 patients with pelvis less than 9 cm. bore living children. Version was applied in 12 and only 5 of the children lived, while all were viable when the forceps had been used, with one exception. He concludes that the use of the forceps is no more dangerous for the mother than version, while it is very much less serious for the child.

**21. Orbito-Ocular Complications of Sinusitis.**—Laperonne is inclined to agree with Luc that all the sinuses are affected simultaneously in a certain number of cases of sinusitis, if not in all, and it is of the utmost importance to examine all the cavities when one is involved. This applies with especial force to the maxillary sinus whose symptoms are apt to mask those of the other sinuses. The anatomic arrangement of the parts explains the frequent coincidence of inflammation of the posterior sinus in case of inflammation of the recesses of the antrum of Highmore, even when there is no fronto-ethmoid suppuration. Some writers classify sinusitis as the fetid variety, due to infection by anaerobes from the teeth, and the non-fetid, due to the ordinary germs entering from the nasal passages. General infection may result from a sinusitis; even broncho-pneumonia has been traced to it in some instances, but orbito-ocular complications can be explained by direct propagation of the process or invasion of germs. One of the most typical examples he relates is that of a young woman who exhibited slight exophthalmus and swelling of the lids during an acute maxillary sinusitis. As these symptoms subsided, evidences of paralysis of the motor oculi developed and on searching, a sphenoidal sinusitis was discovered.

**23. Treatment of Aneurisms of Arch of Aorta.**—Guinard comments on Tuffier's experience with an aneurism of the aorta which he extirpated as described in *THE JOURNAL* of April 12, p. 971. The patient succumbed to secondary hemorrhage from the ligated pedicle which became gangrenous. Guinard thinks that the impossibility of extirpating an aneurism in this location in the majority of cases, and the extreme gravity of this operation in the exceptional instances in which it is practicable, debar it from a place in surgical therapeutics. He prefers simultaneous ligature of the primary carotid and subclavian on the right side. He treated in this way six patients with aneurism of "the base of the neck" and two with aneurisms of the arch of the aorta, before 1896, and since that date six more cases, a total of twelve. Many of the published cases of aneurism supposed to be in the innominate artery were probably located in the arch of the aorta, as the physical signs of these two localizations are nearly identical. The diagnosis can never be more than presumptive except possibly with radioscopy. Consequently, Guinard proclaims that every aneurism of the base of the neck should be treated indiscriminately by a catgut ligature of the two arteries mentioned above. Aneurisms to the left of the innominate trunk are the only ones not amenable to this treatment. In one of his personal cases the dilatation of the aorta had surrounded the brachio-cephalic trunk so that the left subclavian issued directly from the tumor. The carotid and the subclavian were ligated separately. A year after the intervention the patient is still free from attacks of suffocation and from wheezing. In a second case the patient survived only a month, but the tumor subsided after the intervention and death from perforation was averted. In another case the patient was a man 49 years of age. The symptoms of compression in the thorax completely disappeared after the intervention and during the eleven months of observation there was no dyspnea except during unusual exertion. Tardy hemiplegia developed after his first operation of this kind and the patient last operated on has also succumbed. He left the hospital, contrary to directions, the fourth day after the intervention, drove across Paris and climbed to his apartment on the fifth floor, dying suddenly as he lay down on the bed, evidently from fulminating hemorrhage. This catastrophe should not be credited to the intervention, which is simple and comparatively harmless. Guinard has always found the vessels sound even in the immediate vicinity of the tumor and the ligature can be applied with confidence close to it. In one patient the aneurism was supposed to be in the subclavian, but the brachio-cephalic trunk proved to be also involved. The ligature therefore had to be applied outside of the tumor, almost touching it, but the walls of the artery resisted the silk thread like those of a normal vessel. The patient was clinically cured in four months.

**28. Treatment of Tic Douloureux.**—Static electricity seems to have a special action in hysteric tic douloureux, but isolation usually proves the most effectual of all measures in these cases. Potassium bromid is useless in epileptiform tic douloureux, but is sometimes beneficial in cases associated with true epilepsy. Several remarkable cures of this kind have recently been published. Strontium bromid seems to be even more effectual. The bromid must be pure, free from all traces of baryta. Total peripheral resection of the nerve involved has resulted in some cures without recurrence for years, but in case of a primary or secondary "Gasseritis" peripheral resection is, of course, useless. When the pain is in the deep-seated portions of the nerves, the Gasserian ganglion should be resected without wasting time on peripheral measures. Resection of the superior ganglion of the sympathetic is a benign intervention and is proving very effective. Recurrence is liable at first, but the recurrence is much less severe and is liable to yield to therapeutic measures previously quite ineffectual. Resection of the ganglion has a vasomotor influence on the Gasserian ganglion and also on the peripheral branches and bulbar centers of the trigeminal. The harmlessness of this operation and its far-reaching influence promise a future for it in the treatment of certain facial neuralgias.

**29. Double Monstrosities, Operated and Operable.**—Baudouin asserts that there is only a single xiphopagus alive at the present moment, the "Chinese Brothers" with the Barnum and Bailey troupe. They could be separated, as they are evidently operable. Doyen and others who examined them found that the connecting bridge of liver tissue has become almost fibrous from the constant traction, and could easily be divided if the twins desire it when they attain their majority. They are now 17. Baudouin's article is profusely illustrated with cuts of most of the known double human monstrosities. He urges the establishment of a chair of teratology and a museum for the special study of anomalies in this line.

**30. The Salt Soda Solution in Surgery.**—Tavel has been using for ten years a salt-soda solution instead of the usual physiologic saline solution, as he thinks that the fluid should be rendered slightly alkaline as well as saline. It has a remarkable attraction for the leucocytes and thus promotes the physiologic processes of repair while free from the slightest irritating action on the tissues. He aims to stimulate the microbicidal agents of the organism, allowing them free play by moist asepsis with this physiologic salt-soda solution. He reports extensive experimental research which confirms these properties of the salt-soda solution and demonstrates the injury done by "dry asepsis" in many cases, the tendency to adhesions later and the direct harm from exposure of the intestines, etc., to the air. His formula is .75 per cent. sodium chlorid to .25 per cent. dried sodium carbonate. It becomes spontaneously sterile very gradually cold and very rapidly when boiled. He has used it for irrigating the wounds in 80 major operations and the Germans have also introduced it extensively in their clinics. Saenger writes that he has not had a single case of death from infection or physiologic occlusion in 157 laparotomies since he has been using the salt-soda solution, and others report similarly favorable results. Tavel protests against assuming that elaborate operating rooms are necessary for aseptic operations. A small valise for the instruments, dressings, etc., and an hour to transform any room into a suitable operating room, and the surgeon is ready. He boils the tampons, compresses and thread in the salt-soda solution, the instruments in a 2 per cent. solution of borax, and uses a tepid salt-soda solution for irrigating the wound. He lays cloths wrung out of lysol or sublimate solution around the field of operation, with dishes of 1 per 1000 sublimate, or 2.5 per cent. lysol, for disinfecting the hands, rinsing them afterward in the salt-soda solution. With these simple precautions he has operated on numbers of patients at their homes, doing laparotomies, resection of the knee, herniotomies, trephining, etc., and has never had an infection. He urges that students should be especially trained to dispense with costly appliances and learn to "think bacteriologically as well as surgically."

**31. New Method of Operating on Hemorrhoids.**—Potarca describes five cases operated on by the method devised by Veresco and briefly described at the Paris International Medical Congress. A cylinder of cork 8 or 9 cm. long by 3 to 3.5 in diameter is made with a wire handle and is inserted in the dilated anus until the lower end is on a level with it. The dilator is then removed and the anal tissue is pinned to the edge of the cylinder by a row of Carlsbad pins about 1 cm. apart. They pass through the mucosa and the integument at their junction. The latter is then cut with a bistoury just outside the row of pins, the cylinder serving as a support for the incision which severs the skin from the pinned portion. The mucosa containing the hemorrhoidal nodules is left pinned to the cork and the detached surrounding skin and muscle are pushed back. The cork cylinder is then drawn out and the nodules are extirpated or scraped or the entire diseased tract is ablated, the incision proceeding a little at a time as the suture follows it. The cork cylinder affords a convenient handle and support for both incision and suture. The stump is then sutured to the raw edge of the skin encircling the anus which was first incised, and the operation is completed. Internal and external antiseptic precautions are unnecessary with this simple and rapid operation, which insures the clean-

liness and the hemostasis of the field of operation during the entire procedure, by the perfect occlusion of the anal orifice and the stretching of the walls of the anus over the cylinder. The new sphincter is ideal. The article is fully illustrated.

**35. Trophoneurotic Atrophy of the Bones After Inflammations and Traumatism of the Extremities.**—Sudeck has noticed that acute atrophy of the bones is liable to occur after all kinds of inflammations and traumatism of the large and small articulations and also after phlegmons of the soft parts. It usually develops in all the bones below the affected point. It is also liable to occur after contusions and sprains of wrist or ankle, but inflammation of a joint seems to afford the most pronounced predisposition. He considers it a trophoneurotic phenomenon, a traumatic reflex neurosis, and has observed it in some cases as early as four and a half weeks after the primary lesion. It frequently assumes surprising proportions in eight or nine weeks. Radiography shows that the bones are characteristically altered and also the muscles to a less extent. Cyanosis, clamminess and edema of the part aid in the diagnosis, but radiography alone is decisive. The alterations in the bones may persist, but the prognosis is usually favorable. As the severe functional disturbances subside, the shadow of the bones becomes normal once more. Stiffness in the joints, loss of power and occasionally spontaneous pains are symptoms of the condition. It may cause intense pain when weight is borne on the part. This symptom has been observed after even slight traumatism and is undoubtedly due to atrophy of the bone. The latter may also entail curvature of the long bone, as in a case of coxa vara described, consecutive to slight trauma of the neck of the femur. Knowledge of the possibility of such an occurrence, long after the primary traumatism has healed, is important in damage suits, etc. Treatment and prophylaxis should aim to cure the primary lesion as soon as possible. This is usually best accomplished by immobilization, but the bones beyond the lesion should be exercised daily even although movement is painful. Massage and orthopedic exercises should not be delayed until the wound has healed. The harm done to a granulating wound after a phlegmon of the hand, for instance, is not to be compared to the injury that may result from the loss of precious time. Hot local baths are useful and also artificial passive congestion, according to Bier or Helferich. Sudeck prefers the latter. To prevent atrophy of the bones of foot or knee, active movements are necessary but no weight should be borne on the part.

**36. Abortive Treatment of Carbuncle by Subcutaneous Disinfection.**—Bidder does not refer to malignant pustule but to all kinds of furuncles including those with multiple infectious foci. The method of treatment he describes has attracted little attention since his first communication on the subject in 1887, but his experience has been so invariably favorable that he appeals to others to try the method and abort these lesions in the early stages and thus save the patients the usual long siege. He does not wait for the furuncle to ripen, but injects at once a solution of carbolic acid. He inserts a large-sized Pravaz needle, slanting, to the very heart of the furuncle, pushing it through the indurated tissue, the entering point about 5 to 10 mm. from the outer limit of the induration. A few drops of the carbolic solution are then expelled from the syringe and the latter is withdrawn. It is then inserted on the opposite side of the furuncle in the same way, slanting, until the tip reaches the same point as in the first injection. The fluid in the syringe is then expelled and it flows out through the channel left from the first insertion of the needle, or through the central fistula. The procedure does not have to be repeated, and a 2 per cent. aqueous solution of the carbolic acid is strong enough for the purpose, or even a solution of boric acid. The dressings must be changed the next day, but after the plug has been expelled—which occurs exceptionally early with this treatment—the further care is simple. The furuncle is painless immediately after the injection, but then becomes quite painful, with boring and throbbing pains. They subside in the course of an hour and the relief is permanent. The tissues are so hard and tough on the fingers that prompt

incision down to the bone is the most rational treatment for a panaris and he consequently does not recommend this "subcutaneous disinfection" for this kind of a lesion.

**39. Meeting of the Cancer Research Committee.**—Von Leyden delivered his address on the "Parasites of Cancer" which he had presented at the medical congress four days previously and which was reviewed in this connection in *THE JOURNAL* of May 17, p. 1316. Lubarsch observed in reply that local proliferation of the cells can occur in the absence of parasites, and that we have no grounds for the assumption that parasites are able to induce unlimited destructive proliferation of cells. The case of "cabbage hernia" is not an instance in point and has no analogy with the subject. Neither has the affection in rabbits caused by the coccidium. When these parasites penetrate into the epithelial cells of the small biliary passages, the epithelial cells remain entirely passive. There is no proliferation until the passages have become dilated nearly to their maximum by the accumulation of the coccidia and an inflammatory process has been set up with consecutive growth of connective tissue. The parasites are not the direct cause of the cell proliferation in this case. Still further proof is afforded by the fact that the coccidia are found nearly as numerous in the intestines as in the liver, but their presence in the intestine is never accompanied by cell proliferation. There are no signs of mitosis in the cells even when they are crowded with the parasites. The intestine is physiologically accustomed to distension and inflammation is not induced, as in the case of the liver. On the other hand, the conception of a parasitic origin would conflict with what we know of the development of malignant neoplasms in aberrant embryonal germs, in dermoid cysts, in neoplasms in the kidneys, salivary glands, etc. We would have to accept that the parasite has an exclusive affinity for aberrant cells while normally-located cells identical in structure have no attraction for it. This conception is rendered all the more difficult by the fact that these aberrant germs, in the kidney, for instance, are usually encapsulated. It would be hard to understand how the parasite could penetrate into them, through the protecting wall, without inflicting some damage on the kidney tissue proper. The congenital origin of tumors must also be borne in mind, such as embryonal adenosarcomata of the kidneys, rhabdomyosarcomata and tumors in the liver like one noted at von Bergmann's clinic in a ten-day babe. Lubarsch recently found an extremely complicated glomatous, sarcomatous tumor of the skull and brain in a still-born infant whose parents did not exhibit a trace of tumor formation. The parasitic theory would compel the assumption that the parasite had passed through the tissues of the mother or father leaving them intact, and settled in the brain of the fetus where it had induced the development of the neoplasm. He concluded with the statement that many other scientists before von Leyden have noticed the forms which he assumes to be parasites, and no one can say exactly what they are. Some of the forms were reproduced by Schwann and Albrecht in their experimental research on karyorrhexis, in which there could be no question of parasitic action.

**41. Practical Application of Hemolysis in Therapeutics.**—Von Niessen states that he has succeeded in isolating from the blood of 120 syphilitics the bacillus which he considers the causal agent of syphilis. Cultures were derived in every case without exception. He applies the new theoretical and experimental facts that have been learned in regard to hemolysis to the treatment of chronic infectious diseases, syphilis in particular. For instance, mercury paralyzes to a certain extent the vitality of the protoplasm by coagulating the albumin, and this in turn checks the proliferation of the bacteria in the blood. This is the moment to introduce a new element to destroy the bacteria and aid in their elimination. This may be accomplished by balneotherapy. The abrupt changes in temperature favor rupture of the blood corpuscles and pour their contents into the serum. Another means is the artificial hemolysis which is induced by preparations of iodine. The mercury acts as a stimulant to absorption as it is a foreign body, and this action is followed by stimulation of the elim-

inating function in the efforts to throw off the foreign body. He observes that much can be learned that will prove useful in therapeutics from study of the causes and processes of hemolysis.

**42. Advantages of Artificial Mineral Waters.**—Jaworski believes that better results can be obtained from artificially compounded mineral waters, made according to rule and to conform to individual indications, than from natural mineral springs water. He gives a table of eighteen different kinds and urges physicians to recommend them to their patients. They can be taken at home, but it is better for the physician to prescribe at the same time the change of air and scene which will supplement to best advantage the action of the mineral waters. He is not restricted to the places where the natural springs are found, with their expensive and frequently unsalubrious conditions, but can send his patient to the mountains, the seashore, a farm, or wherever he deems best, with his supply of artificial mineral water. It is possible for the physician in a climate and environment especially suited to certain affections, to make a specialty of them and with his artificial mineral waters, to combine all the factors most conducive to a cure. In case one kind of water does not prove effectual, it is far easier to change the water than to travel from one watering-place to another in search of the natural springs.

**44. Etiology and Prophylaxis of Mercurial Stomatitis and Proctitis.**—Bockhart emphasizes the fact that the mercury is not directly responsible for the stomatitis or proctitis, but it produces conditions in the mouth favorable for the proliferation of bacteria, and also conditions in the tissues which diminish their resisting power. This combination entails the resulting lesion, and knowledge of this fact indicates the measures for prophylaxis.

**46. Stypticin as a Local Hemostatic.**—Kaufmann lauds the value of stypticin for this purpose. It is a hydrochlorate of cotarnin, and has proved very useful as an internal remedy for uterine hemorrhage. Kaufmann has been using it for two years as a local hemostatic for the urethra. He combines it with gelatin and finds that it is effective only when the mucosa is more or less abraded as it has no action on sound tissue. He also uses it as a hemostatic for parenchymatous hemorrhage of all kinds and in minor operations.

**47. Treatment of Leucoplasia Bucco-Lingualis.**—Bockhart has had sixty patients with this affection. All were men, all smokers and all were syphilitic. The leucoplasia became aggravated usually under mercurial treatment but could be cured by rinsing out the mouth six to twelve times a day with a .5 to 3 per cent. saline solution. The cure was complete in three months to two years, even when smoking was not entirely abandoned. In some of the patients he had the patches rubbed first with balsam of Peru. His patients carry a bottle of the saline solution in their pocket so as to rinse the mouth frequently during the day. Two of the five, who were thus cured so completely that not a trace is left of the trouble, have resumed smoking. When the patients refuse to give up tobacco, at least during treatment, much benefit can be derived from the saline rinsings, but no permanent cure. He found that the leucoplasia became aggravated after application of caustic measures.

**49. Action of Alkaline Iodids on Patients Deprived of Salt.**—Sellei states from his experience with 30 patients that the deprivation of salt does not prevent iodism when the alkaline iodids are administered. Four of the 28 syphilitics showed intolerance and 1 of the 2 free from syphilis. The variation in the proportion of rhodan in the saliva gives no indication of impending iodism.

**50. Massage of the Urethra.**—Berger uses an instrument for massaging the urethra which consists of a long tube with four grooves at the end about 7 cm. long and 2 mm. wide. The outer end flares into a funnel. When this tube is inserted in the urethra the mucosa presses into the grooves and by gently twisting the tube between the fingers to and fro the walls of the urethra undergo a light but effective massage.

By inserting another tube inside the first it is possible to combine irrigation of the urethra with the massage.

**59. Spinal Analgesia and Distribution of Sensibility According to Segments of Spinal Cord.**—Neugebauer states that since he has succeeded in thoroughly sterilizing his solution of tropa cocain by boiling it, his experience with it has been extremely satisfactory. This includes his last series of 40 cases of spinal analgesia. After-effects of some kind were always noticed, but so slight as to be insignificant. He uses .05 or .03 gm. of the tropa cocain and by careful tests in 100 cases has established that the analgesia occurs in conformity with the laws of segmental innervation from the spinal cord as portrayed in the plates of Kocher's recent work on "Injuries of the Spine." This explains the variations in the sensibility of different regions although the segmental distribution is not so clearly circumscribed as in case of localized injuries of the spine. The analgesia commences in the fourth sacral segment, and spreads in turn to the third and second. The sole of the foot does not become analgetic until some time after the dorsum, and Kocher's plate shows a patch on the sole which is innervated from the first sacral segment. He always found that the analgesia reached higher in the back than in front of the body, and that the serosa of the testicles remained sensitive although the skin might be analgetic, and even after total analgesia of the body.

**60. Pulmonary Embolism in a Case of Placenta Previa.**—In the case described by Voigt the patient was debilitated by four weeks of more or less hemorrhage when brought to the hospital. The birth was partially spontaneous after version and was not accompanied by hemorrhage. The mother was recuperating normally when in about an hour symptoms of embolism of the lungs suddenly developed. The symptoms gradually subsided under camphor and saline infusion, but a similar attack occurred again the fourth day, and an abortive one the day after. The patient recovered after thirty-one days of strict rest in bed and general tonic measures. If the hemorrhage in such cases persists after tamponing the vagina it might be advisable to tampon the collum and also to induce delivery, possibly with Bossi's dilator to save time. The four arms of this dilator when in contact form a single small rod like an ordinary uterine dilator. By turning a thumbscrew in the handle the rod separates into four parts which spread parallel and concentrically to a distance of 8 to 10 cm. [Leopold has recently reported very favorable experiences with it. See THE JOURNAL of May 31, p. 1477.]

**61. Senile Angiomata.**—Raff investigated 500 persons to determine the frequency of angiomata of the skin. He found them on 180. They were rare under 15 but were noted in 18.7 per cent. of the 123 subjects between 20 and 30; in 45.3 per cent. of the 75 persons between 30 and 40, and in 54.2 per cent. of the 61 between 40 and 50. The proportion progressively increased with the age. They occur, therefore, more frequently in the prime of life than has been generally supposed.

**63. Study of Hay Fever.**—Thost made a collective inquiry among the victims of hay fever in the North Sea resorts last summer. Four hundred filled out the circulars he distributed, asking for particulars in regard to their affection. Comparing the data thus obtained corroborates the assumption that hay fever, like asthma, is a reflex neurosis in the region innervated by the nerves of respiration. The olfactory nerve is the one principally involved, its idiosyncrasy in respect to the odors or perfume of certain plants being the essential peculiarity of hay fever. No remedy will cure it once for all in a few applications, but the experience of these four hundred persons demonstrates that it can be improved and even cured and the symptoms avoided by symptomatic and local treatment. The places absolutely free from hay fever are those with scanty, low vegetation without much blossoming.

**64. Behavior of the White Corpuscles in Surgical Affections.**—Wassermann has been making an extensive study of the leucocytosis accompanying surgical affections and announces that he found over 25,000 leucocytes constantly in cases of appendicitis or processes in the vicinity in which the general

symptoms indicated extensive suppuration and also in those in which it existed but was not revealed by any other symptoms. The only exception were the cases so extremely severe that the organism was incapable of reacting with leucocytosis while the other symptoms were so pregnant that no doubt was possible, and also the chronic cases in which the abscess had become walled off. He invariably found that the cases apparently severe but with low or merely transiently high leucocyte count, all recovered without surgical intervention. He proclaims, therefore, that leucocytosis persistently over 25,000 accompanying appendicitis indicates an operation without delay. Suppuration elsewhere was only accompanied by a moderate leucocytosis in the numerous cases examined of paraneuritic or prostatic abscesses, suppurated cervical glands, mastitis and phlegmons, so long as the process was circumscribed. General infections, on the other hand, such as septicemic affections and erysipelas were accompanied by a high leucocytosis. Various bacteria were found in the pus in different cases, the pyocyanus once, the proteus and anaerobics a few times. The species did not seem to have any influence on the leucocytosis which is essentially an increase in the number of polymuclear neutrophile leucocytes. The patients with mild clinical symptoms of appendicitis operated on exclusively from the indication of the persistently high leucocytosis, all proved to have extensive suppuration not revealed by any other sign. This independence of the leucocytosis from the other signs, the temperature, pulse, general aspect and local findings, confers an unprecedented importance upon it as a differentiating measure for suppuration in the ileocecal region.

**66. The Treatment of Venereal Ulcer with Cold.**—Brandweiner reports from Neumann's clinic that very favorable results have been obtained in the treatment of venereal ulcers by freezing them with ethyl chlorid or methyl ethyl, spraying the part with air at the same time. In three to five minutes the ulcer is frozen and a white snow forms on the surface. There is a smarting at first which soon vanishes but reappears for a brief time later. The procedure is repeated once to three times a day, and three or four applications in the majority of cases transform the ulcer into a clean granulating wound with no specific characteristics. These favorable results were observed in 33 out of the 40 cases thus treated. The cold acts by the same mechanism as heat, inducing hyperemia by the reaction, but its application is much more convenient than that of heated air.

**68. Pathology of the Metabolism.**—Freund is chief of the chemical laboratory at the "Rudolfstiftung," and in this article reviews the research on the metabolism in diabetes and other diseases published during the last few years. He remarks that too little attention has been paid hitherto to the pathology of place. By this he means the presence in the body of substances normally its constituents, but not in their normal place. For example, the substances in the blood cells may become harmful when they are released by the destruction of the cells containing them. He compares them to a ship loaded with heavy lumber. If the ship is wrecked the floating lumber becomes a menace to navigation. This pathology of place is probably the principal factor in the development of fever. He suggests a number of lines for future research, among them the determination of the groups of albuminoids which favor the proliferation of certain bacteria, the typhoid bacillus, for instance, so as to avoid them in feeding typhoid patients.

**71. Tests of Antiseptics for the Urine.**—Sachs reports tests of the antiseptic power of substances administered internally to display their action in the urine. He found that after the ingestion of at least 4 gm. of urotropin a day, the urine acquired marked bactericidal power both for bacteria naturally in or added to it. Salicylic acid ranks next in this respect but sometimes causes unpleasant by-effects in the large doses required, while urotropin, even in the dose of 8 gm. long-continued, causes nothing of the kind. Methylene blue, sandal oil, copaiba, camphoric acid and sometimes oil of turpentine also displayed distinct antiseptic power after large doses. No action of the kind could be detected after administration of potassium chlorate, boric acid or folia urae ursi.

**77. New Kind of Acquired Immunity.**—Carbone believes that he has discovered a new means of immunizing the organism against a specific infection by injection of a substance normally in it, the histone, the nucleo-proteid which Kossel discovered in the nucleated red corpuscles in fowls. It has since been established that it is a normal constituent of all the cells in mammals. By the toxic action of the pneumococcus on the cells in the blood, this histone is liberated, and proves one of the principal factors in the development of the infectious syndrome. Carbone now asserts that an injection of histone prepared from the viscera of rabbits, induces the production in the organism of a specific anti-histone immunizing substance which protects the animal against infection with the pneumococcus later. In his tests it never failed to immunize the animal against two or three times the fatal dose of pneumococcus, and against the minimal fatal dose of a streptococcus, and caused much longer survival after infection with anthrax. It may be possible that this new method of immunization may prove useful to supplement the methods of immunizing hitherto in vogue by means of bacteria or their products. He is now engaged in further research in this line, hoping to demonstrate the possibility of aiding the organism in its struggle against disease by accumulating measures of defense, in immunizing it in more than one direction. Carbone describes his technic for testing the serum for its coagulating power which is very much diminished in certain morbid states. He uses an extract of the heads of leeches which allows very exact standardizing.

**79. Alterations in the Sensibility of the Skin in Case of Visceral Lesions.**—Tedeschi describes the changes in the sensibility of the skin which were observed in twenty patients with various visceral lesions. He found that there was a marked coincidence between them and the special lesion, and that the changes occurred in zones similar to those described by Head. They are evidently of reflex spinal origin and may aid in the differentiation of the lesion. A tendency to nervous troubles exaggerates the abnormal sensibility, which may assume the form of hyperalgesia and thermo-hyperesthesia or thermo-hypoesthesia. He gives numerous illustrations showing the constant involvement of certain zones as the accompaniment of certain lesions. For instance, inflammation of the tubes was accompanied by the maximum of hyperalgesia in the twelfth and very rarely in the eleventh dorsal zone, while in appendicitis the maximum was always in the tenth dorsal zone. In case of renal lesions the maximum of hyperalgesia was in the tenth dorsal zone, and if it invaded the eleventh and twelfth, the pelvis and ureters were probably involved. In one case the maximum was in the third sacral segment, and the operation confirmed the presumptive diagnosis of nephrolithiasis, with injury of the bladder from calculi.

**81. Study of the Diazo-Reaction.**—Johnson applied the diazo test in 1221 cases of various diseases. It proved positive in 80.5 per cent. of 728 cases of typhoid fever, in 46 per cent. of pulmonary tuberculosis and in 18.9 per cent. of 90 cases of pneumonia. He thinks that the percentage in typhoid fever is probably actually higher than these figures, as many of the patients were not seen during the early stage of the disease. The diazo-reaction, therefore, can be regarded as an important differentiating measure in dubious cases.

**84. Prophylaxis of Septic Scarlet Fever.**—Sohn calls attention to a case in his experience in which two children in the same family had scarlet fever. One was kept in his usual room while the other, the healthier one, was transferred to a room which had been used eighteen months previously by a person with a persisting suppuration in a fractured leg. The room had been closed since without disinfection. Three days after the child had been placed in this room symptoms of septic scarlet fever developed, fatal in three days, while the other child had merely an ordinary uncomplicated case although the tonsils were hypertrophied. He is inclined to attribute the sepsis to virulent germs in the dust of the spare room.

**88. Typhoid Fever in the City of Mexico.**—Gavino reports that he has recently encountered fifteen cases of typhoid fever, corroborated by the positive serum reaction. This little epi-

demic is confined to a certain quarter of the capital. Typhoid fever is so rare in the City of Mexico that its existence there has been denied.

**89. Antidiphtheria Serum in Treatment of Typhoid Fever.**—Yanez believes that antidiphtheria serum is effective in other infectious diseases and relates two cases of typhoid fever in which the symptoms were rebellious to ordinary measures, but gradually yielded after injections of Roux's serum had been applied.

**90. Hot Air in Treatment of Essential Nasal Hydrorrhea.**—Garaizabal has only two cases to report, but the success was so complete and permanent that he urges others to try this method of treatment when other measures are unavailing. He directed a current of hot air on the hypertrophied lower turbinate bones and after twenty-five applications for ten minutes a day, the flux was entirely cured. He used an apparatus for the purpose, a small metal box holding live coals, a rubber bulb to pump the air through it and a rubber-tipped metal tube in a wooden handle for direct application to the nose.

**91. Prophylaxis of Typhoid Fever.**—Barreneche observes that infection from water can be guarded against and that infection from dust is by far the most dangerous means of contagion of typhoid fever. He cites as an argument to sustain this assertion the fact that the newly graduated doctors when they commence their service in the hospitals are frequently affected by typhoid fever. They ascribe it to auscultation of the back of typhoid fever patients, as the garments and bed linen are so liable to be contaminated by particles of excreta, which float in the air as the patients are moved.

**93. Etiology of Ozena.**—Razquin does not accept the *Bacillus fetidus ozenae* described by Perez as the specific agent of ozena, as it is not encountered in every case and as it may be found in persons exempt from the affection. He has also found it in dogs and suggests that the dog may be the intermediate host between man and man. Razquin has never known of a case of direct transmission of ozena from one person to another, and it occurs in some cases with no previous communication with dogs. On the other hand, the arguments in favor of a sinusitis as the primary cause are numerous and convincing. The fetidity he ascribes to secondary infection which has no specific character. Treatment is more rapid and complete the more accessible the primary lesion. Certain writers state that they were unable to discover any indications of sinusitis at the autopsy of patients with ozena, but study of their reports shows that they failed to examine all the sinuses.

**94. General Infantile Atrophy and Its Treatment with Artificial Serum.**—Vargas has for years been treating children under 2 years of age with general atrophy by means of injections of a 1 per cent. solution of sodium chlorid or of magnesium and sodium sulphate. This treatment entails a rapid cure in the benign form. The grave form is accompanied by intestinal lesions which render recovery a rare exception. He illustrates one case in which a child 2 years old looked almost like a mummy before treatment but gained three kilograms in weight and three centimeters in length by the twentieth day after the subcutaneous injections of 100 c.c. of artificial serum were instituted, repeated night and morning. In thirty minutes after the first injection the arterial tension had increased and the pulse risen from 96 to 125, while the body warmth increased .5 of a degree C.

**96. Serum Treatment of Malignant Anthrax.**—Escudero thinks that the attempt to excise the carbuncle is useless later than half an hour after the inoculation, and is thus impracticable in all cases. It merely adds the needless shock of the operation to the clinical syndrome already present. General treatment should include calomel, local application of a 2 per 1000 solution of bichlorid at 95 F., and serum treatment. The three cases he describes all promptly recovered after one to three injections of serum. Another patient succumbed after excision of the pustule in the neck, notwithstanding the serum treatment.

## Queries and Minor Notes.

### TREATMENT OF TABES BY GOLD OXID, ETC.

ST. LOUIS, MO., May 21, 1902.

*To the Editor:*—In the last issue of THE JOURNAL I saw, on page 1338, an abstract from a Paris journal on the treatment of tabes by gold oxid and phosphovinic acid. Could you please tell me how phosphovinic acid is made and how the gold oxid is combined, and the dose; also how is the iodine administered?

I have been looking up these remedies and can find nothing that will give me any light on the subject.

L. P. W.

*Ans.*—The phosphovinate of gold is stated to be a combination of ethyl phosphoric acid with the oxid of gold. It is a definite chemical compound with 65 per cent. of the stimulant, the gold, to 35 per cent. of the tonic, the phosphoric acid. The compound is rendered soluble by a slight excess of the ethyl phosphoric acid, and the tonic element is enhanced by the addition of the phosphovinate of potassium. The iodine is given in the usual form of an alkaline iodide. Jolly explains its transformation and action as follows: During functional activity the cells become acid and do not return to alkaline until they are at rest again. During the acid phase the iodine of the iodide is liberated and acts as a metalloid iodine, powerfully antiseptic, antitoxic and stimulating. As the cells become alkaline again, the iodine resumes the form of an iodide and ceases to be antitoxic although still retaining weak antimicrobial and antiseptic properties. He has succeeded in administering iodine in the form of an alkaline iodide without intolerance or inconveniences, for as long a period as necessary, by combining it with extract of jugsans in pillular form, as an adjuvant to the gold and phosphoric acid, commencing with small doses of each and increasing them a little every week. Further details in regard to the production of the substances or the dosage are not mentioned. Jolly and Bouland have been studying the application of gold in therapeutics for years.

### WHERE CAN A PHYSICIAN, WHO IS NOT A PHARMACIST, CONDUCT A DRUG STORE?

CHICAGO, May 27, 1902.

*To the Editor:*—Kindly let me know if there are any states in which a physician can own and take charge of a drug store without taking pharmacy board examinations or employing a registered druggist.

Yours truly,

C. JOHNSON.

*Ans.*—Probably in none of the Northern States. A physician was formerly granted that privilege in Missouri, but the law has been changed. It may be that some Southern State or some territory allows this. It will be necessary to address the boards of the several states to secure more definite information than the above.

### MEDICAL REGISTRATION IN FLORIDA.

SUNCOOK, N. H., May 27, 1902.

*To the Editor:*—What is the law for medical registration in the State of Florida? Please send me the address of Secretary of State Board of Examination, if any.

A. M. LAVALLEE, M.D.

*Ans.*—There is no state board yet, but a board for each of the seven judicial circuits, each of which establishes its own standard for examination. A diploma from a recognized school and an examination before one of these boards are required. The secretary of the Fourth Judicial Circuit Board is Dr. Neal Mitchell, Jacksonville.

## Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

*A MANUAL OF SURGICAL TREATMENT.* By W. Watson Cheyne, M.B., F.R.C.S., F.R.S., Professor of Surgery in King's College, London, Surgeon to King's College Hospital, etc., and F. F. Burgard, M.D. and M.S. (Lond.), F.R.C.S., Teacher of Practical Surgery in King's College, London, Surgeon to King's College Hospital, etc. In seven imperial octavo volumes, with illustrations. Volume VI, 498 pages with 124 illustrations. Cloth, \$5.00 net. Philadelphia and New York: Lea Brothers & Co., 1902.

*SANATORIA FOR CONSUMPTIVES.* A Critical and Detailed Description, Together with an Exposition of the Open-Air Hygienic Treatment of Phthisis. By F. Ruffenacht Walters, M.D., M.R.C.P., Fellow of the Royal College of Surgeons, with an Introduction by Sir Richard Douglas Powell, Bart., M.D., F.R.C.P., Second Edition. Cloth, Pp. 446. Price, \$5.00 net. London: Swan Sonnenschein & Co., Ltd., New York: E. P. Dutton & Co., 1902.

*THE PRINCIPLES OF BACTERIOLOGY: A Practical Manual for Students and Physicians.* By A. C. Abbott, M.D., Professor of Hygiene and Bacteriology, and Director of the Laboratory of Hygiene, University of Pennsylvania. Sixth Edition, Enlarged and Thoroughly Revised. With 111 illustrations, of which 26 are colored. Cloth, Pp. 641. Price, \$2.75. Philadelphia and New York: Lea Brothers & Co., 1902.

*THE ROENTGEN RAYS IN MEDICINE AND SURGERY as an Aid in Diagnosis and as a Therapeutic Agent. Designed for the Use of Practitioners and Students.* By Francis H. Williams, M.D.

(Harv.), Graduate of the Massachusetts Institute of Technology. With 410 illustrations. Second Edition. With Enlarged Appendix. Cloth. Pp. 704. Price, \$6.00. New York: The Macmillan Co., 1902.

*PRINCIPLES OF SANITARY SCIENCE AND THE PUBLIC HEALTH, with Special Reference to the Causation and Prevention of Infectious Diseases.* By William T. Sedgwick, Ph.D., Professor of Biology and Lecturer on Sanitary Science and the Public Health in the Massachusetts Institute of Technology, Boston. Cloth. Pp. 368. Price, \$3.00. New York: The Macmillan Co., 1902.

*THIRTY-THIRD ANNUAL REPORT OF THE SECRETARY OF STATE ON THE REGISTRATION OF BIRTHS AND DEATHS, MARRIAGES AND DIVORCES IN MICHIGAN for the Year 1899.* Fred M. Warner, Secretary of State. Edited by Cressey L. Wilbur, M.D., Chief of the Division of Vital Statistics. Cloth. Pp. 157. Lansing, Mich.: Wynkoop-Hallenbeck-Crawford Co., 1902.

*JAHRESBERICHT ueber die Fortschritte in der Lehre von den Pathogenen Mikro-organismen umfassend Bacterien, Pilze und Protozoen.* Unter mitwirkung von Fachgenossen bearbeitet und herausgegeben von Dr. med. P. von Baumgarten und Dr. med. F. Tangl. Sechszenter Jahrgang, 1900. Erste Abtheilung. Paper. Pp. 400. Leipzig: Verlag von S. Hirzel, 1902.

*THE DIAGNOSIS OF SURGICAL DISEASES.* By Dr. E. Albert, Late Director and Professor of the First Surgical Clinic at the University of Vienna. Authorized Translation from the Eighth Enlarged and Revised Edition, by Robert T. Frank, A.M., M.D., with 53 illustrations. Cloth. Pp. 419. Price, \$5.00. New York: D. Appleton & Co., 1902.

*HERNIA, Its Etiology, Symptoms and Treatment.* By W. McAdam Eccles, M.S. (Lond.), F.R.C.S. (Eng.), Senior Assistant Surgeon West London Hospital. Second Edition. Cloth. Pp. 233. Price, \$2.50. New York: Wm. Wood & Co., 1902.

*THE STUDY OF THE PULSE, Arterial, Venous and Hepatic and of the Movements of the Heart.* By James MacKenzie, M.D. (Edin.), Burnley. Cloth. Pp. 325. Price, \$4.50. New York: The Macmillan Co., 1902.

Published under the Auspices of the Board of Trustees.

VOL. XXXVIII.

CHICAGO, SATURDAY, JUNE 14, 1902.

No. 24.

## Address.

### THE PRESIDENT'S ADDRESS.

DELIVERED AT THE FIFTY-THIRD ANNUAL SESSION OF THE  
AMERICAN MEDICAL ASSOCIATION AT SARATOGA  
SPRINGS, N. Y., JUNE 10-13, 1902.

JOHN ALLAN WYETH, M.D., LL.D.  
NEW YORK CITY.

Since the session held at St. Paul a year ago, a former president of this Association, paying the last great debt to nature, has passed

"To where beyond these voices there is peace."

Full of years and beyond the limit allotted by the Psalmist, Professor Edward Mott Moore, born in Rahway, N. J., July 15, 1814, died in Rochester, N. Y., March 3, 1902. He was one of the founders of the New York State Medical Association, a consistent and loyal friend of our national body and of an organized medical profession. Although his achievements in science were of a high order, his life was not circumscribed within the narrow limits of professional work. He was not only a skilful surgeon, bold and original, but more than this, he was a citizen of the highest type. The welfare of his neighbors, of his adopted city, state and the Nation were his. May his noble example be emulated, for it is just as much our duty to be true to the obligations of citizenship as to our profession.

### INTERNATIONAL MEDICAL CONGRESS.

Before dealing with the more urgent matters of this meeting, your attention is called to the Fourteenth International Congress of Medicine which is to be held at Madrid from April 23 to 30, 1903.
